troubleshoot.txt
52 lines
Pre-submit:
Write a few simple test cases if sample is not enough.
Are time limits close? If so, generate max cases.
Is the memory usage fine?
Could anything overflow?
Make sure to submit the right file.
```

```
Wrong answer:
Print your solution! Print debug output, as well.
Are you clearing all data structures between test cases?
Can your algorithm handle the whole range of input?
Read the full problem statement again.
Do you handle all corner cases correctly?
Have you understood the problem correctly?
Any uninitialized variables?
Any overflows?
Confusing N and M, i and j, etc.?
```

- 1 Are you sure your algorithm works?
What special cases have you not thought of?
Are you sure the STL functions you use work as you think?
- 1 Add some assertions, maybe resubmit.
Create some testcases to run your algorithm on.
Go through the algorithm for a simple case.
- 3 Go through this list again.
Explain your algorithm to a teammate.
Ask the teammate to look at your code.
Go for a small walk, e.g. to the toilet.
- 5 Is your output format correct? (including whitespace)
- 8 Rewrite your solution from the start or let a teammate do it.
- 9 Runtime error:
Have you tested all corner cases locally?
Any uninitialized variables?
- 10 Are you reading or writing outside the range of any vector?
Any assertions that might fail?
Any possible division by 0? (mod 0 for example)
- 17 Any possible infinite recursion?
Invalidated pointers or iterators?
Are you using too much memory?
- 22 Debug with resubmits (e.g. remapped signals, see Various).

- 23 Time limit exceeded:
Do you have any possible infinite loops?
What is the complexity of your algorithm?
Are you copying a lot of unnecessary data? (References)
How big is the input and output? (consider scanf)
Avoid vector, map. (use arrays/unordered_map)
What do your teammates think about your algorithm?
- Memory limit exceeded:
What is the max amount of memory your algorithm should need?
Are you clearing all data structures between test cases?

Mathematics (2)

2.1 Equations

$$ax^2+bx+c=0\Rightarrow x=\frac{-b\pm\sqrt{b^2-4ac}}{2a}$$

The extremum is given by $x=-b/2a$.

$$\begin{aligned}ax+by=e\qquad x&=\frac{ed-bf}{ad-bc} \\ cx+dy=f\qquad y&=\frac{af-ec}{ad-bc}\end{aligned}$$

In general, given an equation $Ax=b$, the solution to a variable x_i is given by

$$x_i=\frac{\det A'_i}{\det A}$$

where A'_i is A with the i 'th column replaced by b .

2.2 Trigonometry

$$\begin{aligned}\sin(v+w)&=\sin v\cos w+\cos v\sin w \\ \cos(v+w)&=\cos v\cos w-\sin v\sin w\end{aligned}$$

$$\begin{aligned}\tan(v+w)&=\frac{\tan v+\tan w}{1-\tan v\tan w} \\ \sin v+\sin w&=2\sin\frac{v+w}{2}\cos\frac{v-w}{2} \\ \cos v+\cos w&=2\cos\frac{v+w}{2}\cos\frac{v-w}{2}\end{aligned}$$

$$(V+W)\tan(v-w)/2=(V-W)\tan(v+w)/2$$

where V,W are lengths of sides opposite angles v,w .

$$\begin{aligned}a\cos x+b\sin x&=r\cos(x-\phi) \\ a\sin x+b\cos x&=r\sin(x+\phi)\end{aligned}$$

where $r=\sqrt{a^2+b^2},\phi=\text{atan2}(b,a)$.

2.3 Algebra

Let $H\subseteq\mathbb{Z}_n$ non-empty subset. H is subgroup iff exists d divisor of n such that $H=\hat{d}\mathbb{Z}_n$.

2.4 Geometry

2.4.1 Triangles

Side lengths: a,b,c

Semiperimeter: $p=\frac{a+b+c}{2}$

Area: $A=\sqrt{p(p-a)(p-b)(p-c)}$

Circumradius: $R=\frac{abc}{4A}$

Inradius: $r=\frac{A}{p}$

Length of median (divides triangle into two equal-area triangles):
 $m_a=\frac{1}{2}\sqrt{2b^2+2c^2-a^2}$

Length of bisector (divides angles in two):

$$s_a=\sqrt{bc\left[1-\left(\frac{a}{b+c}\right)^2\right]}$$

Law of sines: $\frac{\sin\alpha}{a}=\frac{\sin\beta}{b}=\frac{\sin\gamma}{c}=\frac{1}{2R}$

Law of cosines: $a^2=b^2+c^2-2bc\cos\alpha$

Law of tangents: $\frac{a+b}{a-b}=\frac{\tan\frac{\alpha+\beta}{2}}{\tan\frac{\alpha-\beta}{2}}$

2.4.2 Quadrilaterals

With side lengths a,b,c,d , diagonals e,f , diagonals angle θ , area A and magic flux $F=b^2+d^2-a^2-c^2$:

$$4A=2ef\cdot\sin\theta=F\tan\theta=\sqrt{4e^2f^2-F^2}$$

For cyclic quadrilaterals the sum of opposite angles is 180° ,
 $ef=ac+bd$, and $A=\sqrt{(p-a)(p-b)(p-c)(p-d)}$.

2.4.3 Spherical coordinates

$$x = r \sin \theta \cos \phi$$
$$y = r \sin \theta \sin \phi$$
$$z = r \cos \theta$$

$$r = \sqrt{x^2 + y^2 + z^2}$$
$$\theta = \arccos(z / \sqrt{x^2 + y^2 + z^2})$$
$$\phi = \operatorname{atan2}(y, x)$$

2.5 Derivatives/Integrals

$$\frac{d}{dx} \arcsin x = \frac{1}{\sqrt{1-x^2}}$$
$$\frac{d}{dx} \arccos x = -\frac{1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx} \tan x = 1 + \tan^2 x$$
$$\frac{d}{dx} \arctan x = \frac{1}{1+x^2}$$

$$\int \tan ax = -\frac{\ln|\cos ax|}{a}$$
$$\int x \sin ax = \frac{\sin ax - ax \cos ax}{a^2}$$

$$\int e^{-x^2} = \frac{\sqrt{\pi}}{2} \operatorname{erf}(x)$$
$$\int x e^{ax} dx = \frac{e^{ax}}{a^2} (ax - 1)$$

Integration by parts

$$\int_a^b f(x)g(x)dx = [F(x)g(x)]_a^b - \int_a^b F(x)g'(x)dx$$

Beta Function

$$B(x,y) = n \int_0^1 t^{nx-1}(1-t^n)^{y-1} dt$$
$$B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$$
$$B(x,y) = B(x,y+1) + B(x+1,y)$$
$$B(x+1,y) = B(x,y) \frac{x}{x+y}$$
$$B(x,y) = B(y,x)$$
$$B(1,x) = \frac{1}{x}$$
$$B(x;a,b) = \int_0^x t^{a-1}(1-t)^{b-1} dt$$
$$B(1;a,b) = B(a,b)$$
$$I_x(a,b) = \frac{B(x;a,b)}{B(a,b)}$$
$$I_0(a,b) = 0 \quad I_1(a,b) = 1 \quad I_x(a,1) = x^a$$

.bashrc .vimrc hash troubleshoot

$$I_x(1,b) = 1 - (1-x)^b$$
$$I_x(a,b) = 1 - I_{1-x}(b,a)$$

$$I_x(a+1,b) = I_x(a,b) - \frac{x^a(1-x)^b}{aB(a,b)}$$

$$I_x(a,b+1) = I_x(a,b) + \frac{x^a(1-x)^b}{bB(a,b)}$$

Gamma Function

$$\Gamma(n) = (n-1)!$$

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$$

$$\Gamma(1/2) = \sqrt{\pi}$$

$$\Gamma(z+1) = z\Gamma(z)$$

2.6 Sums

$$c^a + c^{a+1} + \dots + c^b = \frac{c^{b+1} - c^a}{c - 1}, c \neq 1$$

$$1 + 2 + 3 + \dots + n = \frac{n(n+1)}{2}$$
$$1^2 + 2^2 + 3^2 + \dots + n^2 = \frac{n(2n+1)(n+1)}{6}$$
$$1^3 + 2^3 + 3^3 + \dots + n^3 = \frac{n^2(n+1)^2}{4}$$
$$1^4 + 2^4 + 3^4 + \dots + n^4 = \frac{n(n+1)(2n+1)(3n^2+3n-1)}{30}$$

2.7 Series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots, (-\infty < x < \infty)$$
$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots, (-1 < x \leq 1)$$
$$\sqrt{1+x} = 1 + \frac{x}{2} - \frac{x^2}{8} + \frac{2x^3}{32} - \frac{5x^4}{128} + \dots, (-1 \leq x \leq 1)$$
$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots, (-\infty < x < \infty)$$
$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots, (-\infty < x < \infty)$$

2.8 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x . It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x x p_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2 p_X(x)$ where σ is the standard deviation. If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

Expectation is linear:

$$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$$

For independent X and Y ,

$$V(aX + bY) = a^2 V(X) + b^2 V(Y).$$

2.8.1 Discrete distributions

Binomial distribution

The number of successes in n independent yes/no experiments, each which yields success with probability p is $\operatorname{Bin}(n,p)$, $n = 1, 2, \dots$, $0 \leq p \leq 1$.

$$p(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

$$\mu = np, \sigma^2 = np(1-p)$$

$\operatorname{Bin}(n,p)$ is approximately $\operatorname{Po}(np)$ for small p .

For n large enough, $\operatorname{Bin}(n,p)$ is approximately $\mathcal{N}(np, np(1-p))$.

Negative binomial $\operatorname{NBin}(r,p)$:

$$F(r+k) = 1 - I_p(k+1,r) = I_{1-p}(r,k+1) = F_{\operatorname{Bin}}(k,k+r,p)$$

First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each wich yields success with probability p is $\operatorname{Fs}(p)$, $0 \leq p \leq 1$.

$$p(k) = p(1-p)^{k-1}, k = 1, 2, \dots$$
$$\mu = \frac{1}{p}, \sigma^2 = \frac{1-p}{p^2}$$

Poisson distribution

The number of events occurring in a fixed period of time t if these events occur with a known average rate κ and independently of the time since the last event is $\operatorname{Po}(\lambda)$, $\lambda = t\kappa$.

$$p(k) = e^{-\lambda} \frac{\lambda^k}{k!}, k = 0, 1, 2, \dots$$
$$\mu = \lambda, \sigma^2 = \lambda$$
$$\lambda = rt$$

2.8.2 Continuous distributions

Uniform distribution

If the probability density function is constant between a and b and 0 elsewhere it is $U(a,b)$, $a < b$.

$$f(x) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$$
$$\mu = \frac{a+b}{2}, \sigma^2 = \frac{(b-a)^2}{12}$$

Exponential distribution

The time between events in a Poisson process is $\text{Exp}(\lambda)$, $\lambda > 0$.

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \geq 0 \\ 0 & x < 0 \end{cases}$$
$$\mu = \frac{1}{\lambda}, \sigma^2 = \frac{1}{\lambda^2}$$

Normal distribution

Most real random values with mean μ and variance σ^2 are well described by $\mathcal{N}(\mu, \sigma^2)$, $\sigma > 0$.

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

If $X_1 \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $X_2 \sim \mathcal{N}(\mu_2, \sigma_2^2)$ then

$$aX_1 + bX_2 + c \sim \mathcal{N}(\mu_1 + \mu_2 + c, a^2\sigma_1^2 + b^2\sigma_2^2)$$

2.9 Markov chains

A *Markov chain* is a discrete random process with the property that the next state depends only on the current state. Let X_1, X_2, \dots be a sequence of random variables generated by the Markov process. Then there is a transition matrix $\mathbf{P} = (p_{ij})$, with $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$, and $\mathbf{p}^{(n)} = \mathbf{P}^n \mathbf{p}^{(0)}$ is the probability distribution for X_n (i.e., $p_i^{(n)} = \Pr(X_n = i)$), where $\mathbf{p}^{(0)}$ is the initial distribution.

π is a stationary distribution if $\pi = \pi \mathbf{P}$. If the Markov chain is *irreducible* (it is possible to get to any state from any state), then $\pi_i = \frac{1}{\mathbb{E}(T_i)}$ where $\mathbb{E}(T_i)$ is the expected time between two visits in state i . π_j / π_i is the expected number of visits in state j between two visits in state i .

For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors, π_i is proportional to node i 's degree.

A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and *aperiodic* (i.e., the gcd of cycle lengths is 1). $\lim_{k \rightarrow \infty} \mathbf{P}^k = \mathbf{1} \pi$.

A Markov chain is an A-chain if the states can be partitioned into two sets \mathbf{A} and \mathbf{G} , such that all states in \mathbf{A} are absorbing ($p_{ii} = 1$), and all states in \mathbf{G} leads to an absorbing state in \mathbf{A} . The probability for absorption in state $i \in \mathbf{A}$, when the initial state is j , is $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$. The expected time until absorption, when the initial state is i , is $t_i = 1 + \sum_{k \in \mathbf{G}} p_{ki} t_k$.

Data structures (3)

OrderStatisticTree.h

Description: A set (not multiset!) with support for finding the n^{th} element, and finding the index of an element. To get a map, change nulltype.
Time: $\mathcal{O}(\log N)$

```
#include <bits/extc++.h>
using namespace __gnu_pbds;

template <class T>
using Tree = tree<T, null_type, less<T>, rb_tree_tag,
tree_order_statistics_node_update>;

void example() {
    Tree<int> T, T2; T.insert(8);
    auto it = T.insert(10).first;
    assert(it == T.lower_bound(9));
    assert(T.order_of_key(10) == 1);
    assert(T.order_of_key(11) == 2);
    assert(*T.find_by_order(0) == 8);
    T.join(T2); // assuming T < T2 or T > T2, merge T2 into T
}
```

HashMap.h

Description: Hash map with mostly the same API as unordered_map, but ~3x faster. Uses 1.5x memory. Initial capacity must be a power of 2 (if provided).

```
#include <bits/extc++.h>

// To use most bits rather than just the lowest ones:
struct chash { // large odd number for C
    static const uint64_t C = 11(4e18 * acos(0)) | 71;
    ll operator()(ll x) const { return __builtin_bswap64(x*C); }
};
__gnu_pbds::gp_hash_table<ll,int,chash> H({},{},{},{},{1<<16});
```

SegTree.h

Description: Very fast and quick segment tree. Only useful for easy invariants. 0-indexed. Range queries are half-open.

```
struct SegTree {
    vector<ll> T; int n;
    SegTree(int n) : T(2 * n, -INF), n(n) {}

    void Update(int pos, ll val) {
        for (T[pos += n] = val; pos /= 2)
            T[pos] = f(T[pos * 2], T[pos * 2 + 1]);
    }
    ll Query(int b, int e) {
        ll r1 = -INF, r2 = -INF;
        for (b += n, e += n; b < e; b /= 2, e /= 2) {
            if (b % 2) r1 = max(r1, T[b++]);
            if (e % 2) r2 = max(T[--e], r2);
        }
        return max(r1, r2);
    }
}
```

```
};
```

RMQ.h

Description: Disjoint Sparse Table implementation. Returns $\min_{i=l}^{r-1} v[i]$ in constant time. Can be adapted for other things, like sum or product.
Usage: RMQ rmq(values);
rmq.Query(inclusive, exclusive);
Time: $\mathcal{O}(N \log N + Q)$

```
struct RMQ {
    vector<int> dp[32];

    RMQ(const vector<int> &v) {
        int n = v.size();
        for (int h = 0, l = 1; l <= n; ++h, l *= 2) {
            dp[h].resize(n + 1, 1e9);
            for (int m = l; m < n + 1; m += 2 * l) {
                for (int i = m + l; i <= min(n, m + l); i++)
                    dp[h][i] = min(dp[h][i - l], v[i - l]);
                for (int i = min(n, m) - l; i >= m - l; i--)
                    dp[h][i] = min(v[i], dp[h][i + l]);
            }
        }
    }
    int Query(int l, int r) {
        int h = 31 - __builtin_clz(l ^ r);
        return min(dp[h][l], dp[h][r]);
    }
};
```

BiVec.h

Description: Bi-directional vector (indices in $[-n..n]$).

```
template<typename T>
struct BiVec {
    vector<T> v;
    BiVec(int n, T x = {}) : v(2 * n, x) {}
    T& operator[](int i) { return v[2 * max(i, ~i) + (i < 0)]; }
    void resize(int n) { v.resize(2 * n); }
};
```

CHT.h

Description: Simple convex hull trick. Requires lines to be inserted in increasing slopes order. Queries have to be increasing in x , but it can be relaxed to any values, by doing binary search on the stack.
Time: $\mathcal{O}(1)$ amortized per operation

```
struct CHT {
    deque<tuple<ll, ll, ll>> stk;
    ll ceil(ll a, ll b) { return a / b + (a % b > 0); }

    void InsertLine(ll a, ll b) {
        ll p = -INF;
        while (stk.size()) {
            auto [pp, ap, bp] = stk.back();
            if (ap == a) p = bp > b ? INF : -INF;
            else p = ceil(bp - b, a - ap);
            if (p > pp) break;
            stk.pop_back();
        }
        if (p != INF) stk.emplace_back(p, a, b);
    }
    ll EvalMax(ll x) {
        // prev(upper_bound(all(stk), {x, INF, INF}))
        while ((int)stk.size() > 1 && get<0>(stk[1]) <= x)
            stk.pop_front();
        auto [_, a, b] = stk.front();
        return a * x + b;
    }
}
```

```
};
```

LineContainer.h

Description: Container where you can add lines of the form $kx+m$, and query maximum values at points x . Useful for dynamic programming (“convex hull trick”).

Time: $\mathcal{O}(\log N)$ amortized per operation 0757b0, 30 lines

```
bool QUERY;
struct Line {
    mutable ll a, b, p;
    ll Eval(ll x) const { return a * x + b; }
    bool operator<(const Line& o) const {
        return QUERY ? p < o.p : a < o.a;
    }
};

struct LineContainer : multiset<Line> {
    ll div(ll a, ll b) { return a / b - (a % b < 0); }
    void InsertLine(ll a, ll b) {
        auto isect = [&](auto x, auto y) {
            if (y == end()) return x->p = INF, false;
            if (x->a == y->a) x->p = x->b > y->b ? INF : -INF;
            else x->p = div(x->b - y->b, y->a - x->a);
            return x->p >= y->p;
        };
        auto nx = insert({a, b, 0}), it = nx++, pv = it;
        while (isect(it, nx)) nx = erase(nx);
        if (pv != begin() && isect(--pv, it))
            isect(pv, it = erase(it));
        while ((it = pv) != begin() && (--pv)->p >= it->p)
            isect(pv, erase(it));
    }
    ll EvalMax(ll x) {
        assert(!empty());
        QUERY = 1; auto it = lower_bound({0, 0, x}); QUERY = 0;
        return it->Eval(x);
    }
};
```

ConvexTree.h

Description: Container where you can add lines of the form $a \cdot X + b$, and query maximum values at points x . Useful for dynamic programming. To change to minimum, either change the sign of all comparisons, or just add lines of form $(-a) \cdot X + (-b)$ instead and negate the result.

Time: $\mathcal{O}(\log MAX)$ per operation 1969de, 39 lines

```
struct Line { ll a, b; };

struct ConvexTree {
    struct Node { int dp; int l = -1, r = -1; };
    vector<Node> T; vector<Line> L;
    const int MAX = 1e9; //>= abs(x) for all queries.
    int root = -1;

    ll eval(int i, int x) { return L[i].a * x + L[i].b; }
    int update(int node, int b, int e, int upd) {
        if (node == -1) {
            T.push_back({upd});
            return T.size() - 1;
        }
        int& cur = T[node].dp;
        int m = (b + e) / 2;
        int l = T[node].l, r = T[node].r;
        bool bb = eval(upd, b) > eval(cur, b);
        bool bm = eval(upd, m) > eval(cur, m);
        if (bm) swap(cur, upd);
        if (e - b == 1) { /* do nothing */ }
        else if (bb != bm) l = update(l, b, m, upd);
        else r = update(r, m, e, upd);
    }
};
```

```
T[node].l = l; T[node].r = r;
return node;
}

ll query(int node, int b, int e, int x) {
    if (node == -1) return -INF; //<= a * x + b for all lines.
    int m = (b + e) / 2;
    return max(eval(T[node].dp, x), (x <= m

           recurse(f, c, b, eps / 2, S2);
}
```

```
template<typename Func>
double Quad(Func f, double a, double b, double eps = 1e-8) {
    return recurse(f, a, b, eps, simpson(f, a, b));
}
```

4.2 Optimization

Simplex.h
Description: Solves a general linear maximization problem: maximize $c^T x$ subject to $Ax \leq b, x \geq 0$. Returns -INF if there is no solution, INF if there are arbitrarily good solutions, or the maximum value of $c^T x$ otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that $x = 0$ is viable.
Usage: $A = \{\{1, -1\}, \{-1, 1\}, \{-1, -2\}\}$;
 $b = \{1, 1, -4\}$, $c = \{-1, -1\}$, x ;
 T val = LPSolver(A, b, c).Solve(x);
Time: $\mathcal{O}(NM * \#\text{pivots})$, where a pivot may be e.g. an edge relaxation.
 $\mathcal{O}(2^n)$ in the general case.

}
```

4.2.1 LP dualization

To dualize a LP, add one dual variable for each primal constraint. Function to optimize becomes b^Ty . Then, you have one dual constraint for each primal variable, given by the primal constraints in which they appear.

Primal	Dual
$\max c^Tx$ s.t. $Ax \leq b, x \geq 0$	$\min b^Ty$ s.t. $A^Ty \geq c, y \geq 0$
$\max c^Tx$ s.t. $Ax \leq b$	$\min b^Ty$ s.t. $A^Ty = c, y \geq 0$
$\max c^Tx$ s.t. $Ax = b, x \geq 0$	$\min b^Ty$ s.t. $A^Ty \geq c$

If primal is not unbounded nor infeasible, then neither the dual is, and strong duality holds (i.e., $c^Tx^* = b^Ty^*$).

4.3 Matrices

RowEchelon.h
Description: Converts matrix to reduced row-echelon form. Each of the first r rows will have exactly one non-zero column piv_i , and all columns to the left of piv_i will be zero. To compute rank, do RowEchelon(M).size().
Time: $\mathcal{O}(M^2N)$

```
using ld = double;
using mat = vector<vector<ld>>;
const ld EPS = 1e-9;

pair<vector<int>, int> RowEchelon(mat& A) {
    int n = A.size(), m = A[0].size(), sgn = 1;
    vector<int> piv;
    for (int i = 0, rnk = 0; i < m && rnk < n; ++i) {
        for (int j = rnk + 1; j < n; ++j)
            if (abs(A[j][i]) > abs(A[rnk][i]))
                swap(A[j], A[rnk]), sgn = -sgn;
        if (abs(A[rnk][i]) < EPS) continue;
        for (int j = 0; j < n; ++j) {
            ld coef = A[j][i] / A[rnk][i];
            if (j == rnk || abs(coef) < EPS) continue;
            for (int k = 0; k < m; ++k)
                A[j][k] -= coef * A[rnk][k];
        }
        piv.push_back(i); ++rnk;
    }
    return {piv, sgn};
}
```

SolveLinear.h
Description: Solves $Mx = b$. Set A to be the block matrix $[M|b]$. If there are multiple solutions, returns a sol which has all free variables set to 0.
Time: $\mathcal{O}(M^2N)$

```
"RowEchelon.h"
604f5c, 22 lines

vector<ld> SolveLinear(mat& A) {
    int m = A[0].size() - 1;
    auto piv = RowEchelon(A).first;

            A[i].push_back(i == j);
    auto [piv, sgn] = RowEchelon(A);
    if ((int)piv.size() < n) return false;
    for (int i = 0; i < n; ++i) {
        for (int j = 0; j < n; ++j)
            // For adjunct, do A[i][j + n] *= sgn instead.
            A[i][j + n] /= A[i][i];
        A[i].erase(A[i].begin(), A[i].begin() + n);
    }
    return true;
}
```

4.3.1 Matrix determinant lemma

Suppose A is an invertible square matrix and u, v are column vectors. Then:

$$\det(A + uv^T) = (1 + v^T A^{-1}u)\det(A) = \det(A) + v^T \text{adj}(A)u$$

Here, uv^T is the outer product of u and v . The first and third expressions are equal even when the square matrix A is not invertible.

4.4 Search

GoldenSectionSearch.h
Description: Finds the argument minimizing the function f in the interval $[a, b]$ assuming f is unimodal on the interval, i.e. has only one local minimum. Works equally well for maximization with a small change in the code. See TernarySearch.h in the Various chapter for a discrete version.
Usage: double func(double x) { return 4+x+.3*x*x; }
double xmin = GoldenSectionSearch(-1000,1000,func);
Time: $\mathcal{O}(\log((b - a)/\epsilon))$

```
template<typename Func>
double GoldenSectionSearch(double a, double b, Func f) {
    double r = (sqrt(5) - 1) / 2;
    double x1 = b - r * (b - a), x2 = a + r * (b - a);
    double f1 = f(x1), f2 = f(x2);
    for (int it = 0; it < 64; ++it)
        if (f1 < f2) { // change to > to find maximum
            b = x2; x2 = x1; f2 = f1;
            x1 = b - r * (b - a); f1 = f(x1);
        } else {
            a = x1; x1 = x2; f1 = f2;
            x2 = a + r * (b - a); f2 = f(x2);
        }
    return (a + b) / 2;
}
```

TernarySearch.h

Description: Find the smallest i in $[a, b]$ that maximizes $f(i)$, assuming that $f(a) < \dots < f(i) \geq \dots \geq f(b)$. To reverse which of the sides allows non-strict inequalities, change the $<$ marked with (A) to \leq , and reverse the loop at (B). To minimize f , change it to $>$, also at (B).
Usage: int ind = TernarySearch(0,n,[&](int i){return a[i];});
Time: $\mathcal{O}(\log(b - a))$

```
template<typename Func>
int TernarySearch(int a, int b, Func f) {
    assert(a <= b);
    while (b - a >= 5) {
        int mid = (a + b) / 2;
        if (f(mid) < f(mid + 1)) a = mid; // (A)
        else b = mid;
    }
}
```

```
    }
    for (int i = a + 1; i < b; ++i)
        if (f(a) < f(i)) a = i; // (B)
    return a;
}
```

FracBinarySearch.h

Description: Finds the smallest fraction $p/q \in [0,1]$ such that $f(p/q)$ is true, and $p \leq maxp, q \leq maxq$. You may want to throw an exception from f if it finds an exact solution, in which case $maxp, maxq$ can be removed.
Time: $\mathcal{O}(\log(maxq))$

	6e4dbb, 24 lines
<pre>using ll = long long; struct Frac { ll p, q; }; template<class Func> Frac FracLowerBound(Func f, ll maxq, ll maxp) { Frac lo{0, 1}, hi{1, 1}, mid; // Set hi to 1/0 for (0, inf) if (f(lo)) return lo; assert(f(hi)); for (int it = 0, dir = 1; it < 3 !dir; ++it) { // invariant: f(lo) == !dir, f(hi) == dir for (ll step = 1, adv = 1, now = 0; ; adv ? step *= 2 : step /= 2) { now += step; mid = {lo.p * now + hi.p, lo.q * now + hi.q}; if (abs(mid.p) > maxp mid.q > maxq f(mid) != dir) now -= step, adv = 0; if (!step) break; } if (mid.p != hi.p) it = 0; hi = lo; lo = mid; dir = !dir; } // (lo, hi) are consecutive with f(lo) == 0, f(hi) == 1 return hi; }</pre>	

4.5 Fourier transforms

FFT.h

Description: Cooley-Tukey-like fft. For better precision, see "NTT.h".
Time: $\mathcal{O}(N \log N)$

	72a787, 14 lines
<pre>void DFT(vector<complex<double>> &a, bool rev) { int n = a.size(); auto b = a; for (int step = n / 2; step; step /= 2) { for (int i = 0; i < n / 2; i += step) { auto wn = polar(1.0, 2.0 * M_PI * (rev ? -i : i) / n); for (int j = 0; j < step; ++j) { auto u = a[i * 2 + j], v = wn * a[i * 2 + j + step]; b[i + j] = u + v; b[i + n / 2 + j] = u - v; } } swap(a, b); } if (rev) for (auto& x : a) x /= n; }</pre>	

NTT.h

Description: Cooley-Tukey-like ntt. Discrete Fourier modulo specific nice primes of the form $2^a b + 1$, where the convolution result has size at most 2^a . Takes around 100ms on $N = 5 \cdot 10^5$ on library-checker.
Time: $\mathcal{O}(N \log N)$

"../number-theory/ModInt.h"	4fcccc, 22 lines
<pre>// Good MOD: (119 << 23 + 1), (5 << 25 + 1), (5LL << 55 + 1) void DFT(vector<ModInt> &a, bool rev) { int n = a.size(); auto b = a; // assert(!(n & (n - 1))); ModInt g = 1; while (g.pow((MOD - 1) / 2) == 1) g = g + 1; if (rev) g = g.inv();</pre>	

<pre>for (int step = n / 2; step; step /= 2) { ModInt w = g.pow((MOD - 1) / (n / step)), wn = 1; for (int i = 0; i < n / 2; i += step) { for (int j = 0; j < step; ++j) { auto u = a[2 * i + j], v = wn * a[2 * i + j + step]; b[i + j] = u + v; b[i + n / 2 + j] = u - v; } wn = wn * w; } swap(a, b); } if (rev) { auto n1 = ModInt(n).inv(); for (auto& x : a) x = x * n1; }</pre>	
---	--

FST.h

Description: Transform to a basis with fast convolutions of the form $c[x \oplus y] += a[x] \cdot b[y]$, where \oplus is one of AND, OR, XOR. The size of a must be a power of two.
Time: $\mathcal{O}(N \log N)$

	eb980e, 13 lines
<pre>void DFT(vector<int>& a, bool rev) { int n = a.size(); // assert(!(n & (n - 1))); for (int step = 1; step < n; step *= 2) for (int i = 0; i < n; i += 2 * step) for (int j = i; j < i + step; ++j) { auto u = a[j], v = a[j + step]; tie(a[j], a[j + step]) = rev ? make_pair(v - u, u) : make_pair(v, u + v); // AND rev ? make_pair(v, u - v) : make_pair(u + v, u); // OR make_pair(u + v, u - v); // XOR } if (rev) for (auto& x : a) x /= n; // XOR only }</pre>	

SubsetConv.h

Description: Neat trick to compute $c[x[y] += a[x] \cdot b[y]$, where x and y satisfy $x \& y = 0$. Use with "OR" FST transform. The idea is to do FST convolutions and discard the results unless the number of bits of the result equals the sums of the bits of the multiplicants. The idea can probably be adapted to other similar problems.
Time: $\mathcal{O}(N \log^2 N)$ (around 2s for $N = 2^{20}$)

"FST.h"	f85131, 23 lines
<pre>using Poly = vector<int>;</pre>

    }
    for (int i = 0; i < n; ++i)
        ans = ans + r[i + 1] * first[i];
    return ans;
}
```

4.7.1 Char. polynomial

If $a_n = c_1 a_{n-1} + \dots + c_k a_{n-k}$, and r_1, \dots, r_k are distinct roots of $x^k + c_1 x^{k-1} + \dots + c_k$, there are d_1, \dots, d_k s.t.

$$a_n = d_1 r_1^n + \dots + d_k r_k^n.$$

Non-distinct roots r become polynomial factors, e.g.

$$a_n = (d_1 n + d_2) r^n.$$

Number theory (5)

5.1 Modular arithmetic

ModInt.h

Description: Operators for modular arithmetic. You need to set MOD to some number first and then you can use the structure.

0214fc, 16 lines

```
const int MOD = 17; // change to something else
struct ModInt {
    int x;
    ModInt(int x = 0) : x(x + (x < 0) * MOD - (x >= MOD) * MOD){}
    ModInt operator+(ModInt o) { return x + o.x; }
    ModInt operator-(ModInt o) { return x - o.x; }
```

```
    ModInt operator*(ModInt o) { return 1LL * x * o.x % MOD; }
    ModInt operator/(ModInt b) { return *this * b.inv(); }
    ModInt inv() { return pow(MOD - 2); }
    ModInt pow(long long e) {
        if (!e) return 1;
        ModInt r = pow(e / 2); r = r * r;
        return e % 2 ? *this * r : r;
    }
    bool operator==(ModInt o) { return x == o.x; }
};
```

ModMulLL.h

Description: Calculate $a \cdot b \bmod c$ (or $a^b \bmod c$) for $0 \leq a, b \leq c \leq 7.2 \cdot 10^{18}$.
Time: $\mathcal{O}(1)$ for modmul, $\mathcal{O}(\log b)$ for modpow

a34b1e, 12 lines

```
typedef unsigned long long ull;
```

```
ull modmul(ull a, ull b, ull mod) {
    ll ret = a * b - mod * ull(1LL / mod * a * b);
    return ret + mod * (ret < 0) - mod * (ret >= (ll)mod);
}
ull modpow(ull b, ull e, ull mod) {

  x = x * gs % p;
  b = b * g % p;
}
```

5.2 Primality

MillerRabin.h
Description: Deterministic Miller-Rabin primality test. Guaranteed to work for numbers up to $7 \cdot 10^{18}$; for larger numbers, use Python and extend A randomly.
Time: 7 times the complexity of $a^b \pmod c$.

```
"ModMuLL.h"
583580, 12 lines

bool IsPrime(ull n) {
  if (n < 2 || n % 6 != 1) return n == 2 || n == 3;
  ull A[] = {2, 325, 9375, 28178, 450775, 9780504, 1795265022},

  l.insert(l.end(), r.begin(), r.end());
  return l;
}
```

5.3 Divisibility

5.3.1 Bézout's identity

For $a \neq 0, b \neq 0$, then $d = \gcd(a,b)$ is the smallest positive integer for which there are integer solutions to

$$ax + by = d$$

$$\left(x + \frac{kb}{\gcd(a,b)}, y - \frac{ka}{\gcd(a,b)}\right), \quad k \in \mathbb{Z}$$

5.4 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$$a = k \cdot (m^2 - n^2), \quad b = k \cdot (2mn), \quad c = k \cdot (m^2 + n^2),$$

with $m > n > 0, k > 0, m \perp n$, and either m or n even.

5.5 Primes

$p = 962592769$ is such that $2^{21} \mid p - 1$, which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than 1 000 000.

Primitive roots exist modulo any prime power p^a , except for $p = 2, a > 2$, and there are $\phi(\phi(p^a))$ many. For $p = 2, a > 2$, the group $\mathbb{Z}_{2^a}^\times$ is instead isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_{2^{a-2}}$.

5.6 Estimates

$$\sum_{d|n} d = \mathcal{O}(n \log \log n).$$

The number of divisors of n is at most around 100 for $n < 5e4$, 500 for $n < 1e7$, 2000 for $n < 1e10$, 200 000 for $n < 1e19$.

5.7 Mobius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu(d)g(n/d)$$

Other useful formulas/forms:

$$\sum_{d|n} \mu(d) = [n = 1] \text{ (very useful)}$$

$$g(n) = \sum_{n|d} f(d) \Leftrightarrow f(n) = \sum_{n|d} \mu(d/n)g(d)$$

$$g(n) = \sum_{1 \leq m \leq n} f(\lfloor \frac{n}{m} \rfloor) \Leftrightarrow f(n) = \sum_{1 \leq m \leq n} \mu(m)g(\lfloor \frac{n}{m} \rfloor)$$

Combinatorial (6)

6.1 Permutations

6.1.1 Factorial

n	1	2	3	4	5	6	7	8	9	10
$n!$	1	2	6	24	120	720	5040	40320	362880	3628800
n	11	12	13	14	15	16	17			
$n!$	4.0e7	4.8e8	6.2e9	8.7e10	1.3e12	2.1e13	3.6e14			
n	20	25	30	40	50	100	150	171		
$n!$	2e18	2e25	3e32	8e47	3e64	9e157	6e262	>DBLMAX		

IntPerm.h

Description: Permutation -> integer conversion. (Not order preserving.) Integer -> permutation can use a lookup table.
Time: $\mathcal{O}(n)$

```
int permToInt(vi& v) {
    int use = 0, i = 0, r = 0;
    for(int x:v) r = r * ++i + __builtin_popcount(use & -(1<<x)),
        use |= 1 << x;
    return r;
}
```

044568, 6 lines

6.1.2 Cycles

Let $g_S(n)$ be the number of n -permutations whose cycle lengths all belong to the set S . Then

$$\sum_{n=0}^\infty g_S(n) \frac{x^n}{n!} = \exp\left(\sum_{n\in S} \frac{x^n}{n}\right)$$

6.1.3 Derangements

Permutations of a set such that none of the elements appear in their original position.

$$D(n) = (n-1)(D(n-1)+D(n-2)) = nD(n-1) + (-1)^n = \left\lfloor \frac{n!}{e} \right\rfloor$$

6.1.4 Burnside’s lemma

Given a group G of symmetries and a set X , the number of elements of X up to symmetry equals

$$\frac{1}{|G|} \sum_{g\in G} |X^g|,$$

where X^g are the elements fixed by g ($g.x = x$).

If $f(n)$ counts “configurations” (of some sort) of length n , we can ignore rotational symmetry using $G = \mathbb{Z}_n$ to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n,k)) = \frac{1}{n} \sum_{k|n} f(k) \phi(n/k).$$

6.2 Partitions and subsets

6.2.1 Partition function

Number of ways of writing n as a sum of positive integers, disregarding the order of the summands.

$$p(0) = 1, \; p(n) = \sum_{k\in\mathbb{Z}\setminus\{0\}} (-1)^{k+1} p(n-k(3k-1)/2)$$

$$p(n) \sim 0.145/n \cdot \exp(2.56\sqrt{n})$$

n	0	1	2	3	4	5	6	7	8	9	20	50	100
$p(n)$	1	1	2	3	5	7	11	15	22	30	627	$\sim 2\text{e}5$	$\sim 2\text{e}8$

6.2.2 Lucas’ Theorem

Let n, m be non-negative integers and p a prime. Write $n = n_k p^k + \dots + n_1 p + n_0$ and $m = m_k p^k + \dots + m_1 p + m_0$. Then $\binom{n}{m} \equiv \prod_{i=0}^k \binom{n_i}{m_i} \pmod{p}$.

6.2.3 Binomials

multinomial.h

Description: Computes $\binom{k_1+\dots+k_n}{k_1,k_2,\dots,k_n} = \frac{(\sum k_i)!}{k_1!k_2!\dots k_n!}$.

```
ll multinomial(vi& v) {
    ll c = 1, m = v.empty() ? 1 : v[0];
    rep(i,1,sz(v)) rep(j,0,v[i])
        c = c * ++m / (j+1);
    return c;
}
```

a0a312, 6 lines

6.3 General purpose numbers

6.3.1 Bernoulli numbers

EGF of Bernoulli numbers is $B(t) = \frac{t}{e^t-1}$ (FFT-able).

$$B[0,\dots] = [1, -\tfrac{1}{2}, \tfrac{1}{6}, 0, -\tfrac{1}{30}, 0, \tfrac{1}{42}, \dots]$$

Sums of powers:

$$\sum_{i=1}^n n^m = \frac{1}{m+1} \sum_{k=0}^m \binom{m+1}{k} B_k \cdot (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\begin{aligned} \sum_{i=m}^\infty f(i) &= \int_m^\infty f(x)dx - \sum_{k=1}^\infty \frac{B_k}{k!} f^{(k-1)}(m) \\ &\approx \int_m^\infty f(x)dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m)) \end{aligned}$$

6.3.2 Stirling numbers of the first kind

Number of permutations on n items with k cycles.

$$\begin{aligned} c(n,k) &= c(n-1,k-1) + (n-1)c(n-1,k), \; c(0,0) = 1 \\ \sum_{k=0}^n c(n,k) x^k &= x(x+1) \dots (x+n-1) \end{aligned}$$

$$c(8,k) = 8, 0, 5040, 13068, 13132, 6769, 1960, 322, 28, 1$$

$$c(n,2) = 0, 0, 1, 3, 11, 50, 274, 1764, 13068, 109584, \dots$$

6.3.3 Eulerian numbers

Number of permutations $\pi \in S_n$ in which exactly k elements are greater than the previous element. k j :s s.t. $\pi(j) > \pi(j+1)$, $k+1$ j :s s.t. $\pi(j) \geq j$, k j :s s.t. $\pi(j) > j$.

$$E(n,k) = (n-k)E(n-1,k-1) + (k+1)E(n-1,k)$$

$$E(n,0) = E(n,n-1) = 1$$

$$E(n,k) = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k+1-j)^n$$

6.3.4 Stirling numbers of the second kind

Partitions of n distinct elements into exactly k groups.

$$S(n,k) = S(n-1,k-1) + kS(n-1,k)$$

$$S(n,1) = S(n,n) = 1$$

$$S(n,k) = \frac{1}{k!} \sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n$$

6.3.5 Bell numbers

Total number of partitions of n distinct elements. $B(n) = 1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \dots$. For p prime,

$$B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}$$

6.3.6 Labeled unrooted trees

on n vertices: n^{n-2}
on k existing trees of size n_i : $n_1 n_2 \dots n_k n^{k-2}$
with degrees d_i : $(n-2)! / ((d_1-1)! \dots (d_n-1)!)$

6.3.7 Catalan numbers

$$C_n = \frac{1}{n+1} \binom{2n}{n} = \binom{2n}{n} - \binom{2n}{n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, \; C_{n+1} = \frac{2(2n+1)}{n+2} C_n, \; C_{n+1} = \sum C_i C_{n-i}$$

$$C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$$

- sub-diagonal monotone paths in an $n \times n$ grid.
- strings with n pairs of parenthesis, correctly nested.
- binary trees with with $n+1$ leaves (0 or 2 children).
- ordered trees with $n+1$ vertices.
- ways a convex polygon with $n+2$ sides can be cut into triangles by connecting vertices with straight lines.
- permutations of $[n]$ with no 3-term increasing subseq.

Graph (7)

7.1 General

SCC.h

Description: Finds strongly connected components in a directed graph. If vertices u, v belong to the same component, we can reach u from v and vice versa.
Usage: SCC(graph, [&](auto& v) { ... }) visits all components in reverse topological order.
Time: $\mathcal{O}(E+V)$

```
template<class CB>
void SCC(vector<vector<int>>& graph, CB cb) {
    int n = graph.size(), timer = 0;
    vector<int> val(n, 0), stk, cont;

    function<int(int)> dfs = [&](int node) {
        int low; low = val[node] = ++timer;
        int sz = stk.size(); stk.push_back(node);
```

1deb0c, 22 lines

```
for (auto vec : graph[node])
    if (val[vec] != -1)
        low = min(low, val[vec] ? : dfs(vec));
if (low == val[node]) {
    cont = {stk.begin() + sz, stk.end()};
    for (auto x : cont) val[x] = -1;
    cb(cont); stk.resize(sz);
} else val[node] = low;
return low;
};
for (int i = 0; i < n; ++i)
    if (val[i] != -1)
        dfs(i);
}
```

BCC.h

Description: Finds all biconnected components in an undirected multi-graph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge, i.e., not part of any cycle. HOWEVER, note that we are outputting bridges as BCC's here, because we might be interested in vertex bcc's, not edge bcc's.

To get the articulation points, look for vertices that are in more than 1 BCC. To get the bridges, look for biconnected components with one edge
Time: $\mathcal{O}(E + V)$

```
template<typename CB>
void BCC(vector<vector<pair<int, int>>>& graph, CB&& cb) {
    int timer = 0, n = graph.size();
    vector<int> val(n, -1);
    vector<tuple<int, int, int>> stk, cont;
```

```
function<int(int, int)> dfs = [&](int node, int pei) {
    int ret; ret = val[node] = timer++;
    for (auto [vec, ei] : graph[node]) {
        if (ei == pei) continue;
        if (val[vec] != -1) {
            ret = min(ret, val[vec]);
            if (val[vec] < val[node])
                stk.emplace_back(node, vec, ei);
        } else {
            int sz = stk.size(), low = dfs(vec, ei);
            ret = min(ret, low);
            stk.emplace_back(node, vec, ei);
            if (low >= val[node]) {
                cont = {stk.begin() + sz, stk.end()};
                cb(cont); stk.resize(sz);
            }
        }
    }
    return ret;
};
for (int i = 0; i < n; ++i)
    if (val[i] == -1)
        dfs(i, -1);
}
```

2SAT.h

Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type $(a \vee b) \wedge (!a \vee c) \wedge (d \vee !b) \wedge \dots$ becomes true, or reports that it is unsatisfiable. Returns empty vector if no solution. Negated variables are represented by bit-inversions (~x).

Usage: TwoSat sat(4); // number of variables
sat.Either(0, ~3); // Var 0 is true or var 3 is false
sat.SetValue(2); // Var 2 is true
sat.AtMostOne({0,~1,2}); // <= 1 of vars 0, ~1 and 2 are true
sat.Solve(); // Returns solution

BCC 2SAT SmallDijkstra EulerWalk

Time: $\mathcal{O}(N + E)$, where N is the number of boolean variables, and E is the number of clauses.

```
<../data-structures/BitVec.h>
0c6cb5, 53 lines

struct TwoSat {

    }
    return ans;
}
};
```

SmallDijkstra.h

Description: Dijkstra optimization on graphs with small costs. Edges of graph must have costs in the range $[0, \text{lim})$. Also works for cases where maximum distance is bounded by something small (just set $\text{lim} = \text{maxd} + 1$). Particularly useful for linear 0 – 1 BFS.

Time: $\mathcal{O}(V + E + \text{maxd})$.

```
template<typename Graph>
vector<int> Dijkstra(Graph& graph, int src, int lim) {
    vector<vector<int>> qs(lim);
    vector<int> dist(graph.size(), -1);
```

```
dist[src] = 0; qs[0].push_back(src);
for (int d = 0, maxd = 0; d <= maxd; ++d) {
    for (auto& q = qs[d % lim]; q.size(); ) {
        int node = q.back(); q.pop_back();
        if (dist[node] != d) continue;
        for (auto [vec, cost] : graph[node]) {
            if (dist[vec] != -1 && dist[vec] <= d + cost) continue;
            dist[vec] = d + cost;
            qs[(d + cost) % lim].push_back(vec);
            maxd = max(maxd, d + cost);
        }
    }
}
return dist;
}
```

EulerWalk.h

Description: Eulerian undirected/directed path/cycle algorithm. For a directed/undirected graph. For each path/cycle found, calls a callback. You can check cycle by checking path endpoints.

Time: $\mathcal{O}(V + E)$.

```
bool DIR = false;

struct EulerWalk {
    int n;
    vector<vector<pair<int, int>>> graph;
    vector<int> cap, walk, buf, deg;

    EulerWalk(int n) : n(n), graph(n + 1), deg(n + 1) {}

    int AddEdge(int a, int b, int c = 1) {
        int ret = cap.size();
        graph[b].emplace_back(a, ret);
        if (!DIR) graph[a].emplace_back(b, ret);
        cap.push_back(c);
        deg[a] += c; deg[b] -= c;
        if (!DIR) deg[a] %= 2, deg[b] %= 2;
        return ret;
    }

    void dfs(int node) {
        while (graph[node].size()) {
            auto [vec, ei] = graph[node].back();
            if (!cap[ei]) graph[node].pop_back();
            else --cap[ei], dfs(vec);
        }
        walk.push_back(node);
    }

    template<typename CB>
    void Go(CB&& cb) {
        for (int i = 0; i <= n; ++i) {
            if (deg[i] < 0) Add(i, n, -deg[i]);
            if (deg[i] > 0) Add(n, i, +deg[i]);
            assert(deg[i] == 0);
        }
        for (int i = n; i >= 0; --i)
            dfs(i), walk.push_back(n);
        for (int i = 0, j = 0; i < (int)walk.size(); i = j + 1) {
            for (j = i; walk[j] < n; ++j);
            if (j - i > 1) cb({walk.begin() + i, walk.begin() + j});
        }
    }
};
```

MaximumClique.h

Description: Quickly finds a maximum clique of a graph (given as symmetric bitset matrix; self-edges not allowed). Can be used to find a maximum independent set by finding a clique of the complement graph.
Time: Runs in about 1s for n=155 and worst case random graphs (p=.90). Runs faster for sparse graphs.

```
typedef vector<bitset<200>> vb;
struct Maxclique {
    double limit=0.025, pk=0;
    struct Vertex { int i, d=0; };
    typedef vector<Vertex> vv;
    vb e;

MatroidIntersection.h

Description: Weighted Matroid intersection algorithm. Given two matroids M_1 and M_2 on the same set $[0..n]$, computes the maximal independent set on both matroids. Matroids are functions which should return vector of elements that can be added to an existing solution. For unweighted version, set $w[i] = 0$.

Usage: Color C(colors); Forest F(n, edges);

auto sol = MatroidIntersection(C, F, w);

Time: Generally $\mathcal{O}(M^2N)$, where M is the solution size.

0345ef, 42 lines

}
```

7.2.1 Flows with demands

To solve flow with demands where $l(u, v) \leq f(u, v) \leq h(u, v)$, first find feasible flow by solving max $S' - T'$ flow on network:

- $c'(S', v) = \sum_{u \in V} l(u, v)$ for all $v \in V$
- $c'(v, T') = \sum_{w \in V} l(v, w)$ for all $v \in V$
- $c'(u, v) = h(u, v) - l(u, v)$ for all $(u, v) \in E$
- $c'(T, S) = \infty$

Assert that flow equals $\sum l(u, v)$. Next, solve max flow on ”residual” graph given flow function (take each edge $(u, v) \in E$ and set $c(u, v) = h(u, v) - l(u, v), f(u, v) = f'(u, v)$). For minimum flow, find max $T - S$ flow on the same network.

7.5 Math

7.5.1 Number of Spanning Trees

Create an $N \times N$ matrix mat , and for each edge $a \rightarrow b \in G$, do $\text{mat}[a][b]--$, $\text{mat}[b][b]++$ (and $\text{mat}[b][a]--$, $\text{mat}[a][a]++$ if G is undirected). Remove the i th row and column and take the determinant; this yields the number of directed spanning trees rooted at i (if G is undirected, remove any row/column).

7.5.2 Erdős–Gallai theorem

A simple graph with node degrees $d_1 \geq \dots \geq d_n$ exists iff $d_1 + \dots + d_n$ is even and for every $k = 1 \dots n$,

$$\sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^n \min(d_i, k).$$

Geometry (8)

  if (OnSegment(c, d, b)) s.insert(b);
  if (OnSegment(a, b, c)) s.insert(c);
  if (OnSegment(a, b, d)) s.insert(d);
  return {s.begin(), s.end()};
}
```

LineDist.h

Description:

Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative on right as seen from a towards b. Does products up to $O(X^3)$.

WARNING: If $a = b$ nan is returned, although don't rely on that.

"Point.h"

32cf2c, 7 lines

```
double LineDistance(Point a, Point b, Point p) {
  return det(a, b, p) / abs(b - a);
}
// Projects point p on line (a, b)
Point ProjectPointOnLine(Point p, Point a, Point b) {
  return a + (b - a) * dot(p - a, b - a) / norm(b - a);
}
```

SegDist.h

Description:

Returns the shortest distance between point p and the line segment from point s to e.

Usage: Point a{0, 0}, b{2, 2}, p{1, 1};

bool onSegment = SegmentDistance(p, a, b) < EPS;

"Point.h"

e35a3d, 12 lines

```
double SegmentDistance(Point p, Point a, Point b) {
  if (sgn(abs(a - b))) return abs(p - a);
  double d = norm(b - a), t = clamp(dot(p - a, b - a), 0., d);
  return abs((p - a) * d - (b - a) * t) / d;
}

  if (sgn(d) == 0) return a;
  double r = dot(p - a, b - a) / d;
  return (r < 0) ? a : (r > 1) ? b : (a + (b - a) * r);
}
```

OnSeg.h

Description: Returns true iff p lies on the line segment from s to e. Use (segDist(s,e,p)<=epsilon) instead when using Point<double>.

"Point.h"

88cc3d, 3 lines

```
bool OnSegment(P s, P e, P p) {
    return sgn(det(p, s, e)) == 0 && sgn(dot(s - p, e - p)) <= 0;
}
```

LinTrans.h

Description:
Apply the affine transformation (translation, rotation and scaling) which maps $(p, q) \rightarrow (fp, fq)$ to point r .

"Point.h"1d3397, 3 lines

Point LinTrans(Point p, Point q, Point fp, Point fq, Point r) {
 return fp + (r - p) * (fq - fp) / (q - p);
}

8.2 Polygons

PolyCenter.h

Description: Computes the center of mass of a polygon.

"Point.h"e2a1f0, 10 lines

Point PolygonCenter(vector<Point> P) {
 int n = P.size();
 Point O = 0.; ld A = 0.;
 for (int i = 0, j = n - 1; i < n; j = i++) {
 O += (P[i] + P[j]) * cross(P[j], P[i]);
 A += cross(P[j], P[i]);
 }
 O = O / 3. / A;
 return O;
}

InsidePoly.h

Description: Returns true if p lies within the polygon described by the points between iterators begin and end. Returns 0 if on polygon, 1 if inside polygon and -1 if outside. Answer is calculated by counting the number of intersections between the polygon and a line going from p to infinity in the positive x-direction. The algorithm uses products in intermediate steps so watch out for overflow. If points within epsilon from an edge should be considered as on the edge replace the line "if (onSegment..." with the comment bellow it (this will cause overflow for int and long long).

Time: $\mathcal{O}(n)$

"Point.h", "OnSegment.h"151734, 10 lines

int InsidePolygon(vector<Point>& P, const Point& p) {
 int ic = 0, n = P.size();

MEC.h

Description: Computes the minimum circle that encloses a set of points.

Time: expected $\mathcal{O}(N)$

d6eaa5, 20 lines

Circle MEC(vector<Point>& pts) { assert(pts.size()); shuffle(pts.begin(), pts.end(), rng); int n = pts.size(); Point c = pts[0]; double r = 0; for (int i = 0; i < n; ++i) { if (abs(c - pts[i]) < r * (1 + EPS)) continue; c = pts[i]; r = 0.; for (int j = 0; j < i; ++j) { if (abs(c - pts[j]) < r * (1 + EPS)) continue; c = (pts[i] + pts[j]) * 0.5; r = abs(c - pts[i]); for (int k = 0; k < j; ++k) { if (abs(c - pts[k]) < r * (1 + EPS)) continue; c = CircumCenter(pts[i], pts[j], pts[k]); r = abs(c - pts[i]); } } } return {c, r}; }

8.4 Misc. Point Set Problems

PointLocation.h

Description: Given a list of points P, a list of segments E, and a list of query points Q, computes for each point the segment that is closest from each query point looking down (towards y = -INF). Returns -1 if no such segment is found, -2 if query point coincides with input point, or the index of the segment otherwise. Products are up to $\mathcal{O}(X^2)$.

Time: $\mathcal{O}((N + Q) \log N)$

WARNING: Segments have to be non-intersecting and non-degenerate.

"Point.h"18033c, 41 lines

vector<int> PointLocation(vector<Point>& P, vector<array<int, 2>>& E, vector<Point>& Q) { int n = P.size(), m = E.size(), q = Q.size(); // Make sweepline events. vector<tuple<Point, int, int>> evs;

P.pop_back(); E.pop_back();

return ans;

}

DCEL.h

Description: Computes the faces of a planar graph. Returns a permutation nxt where $nxt[i]$ is the next edge in the same face as edge i . Faces are trigonometric ordered. It doesn't compute a DCEL per se, but any other information can be recovered (origin is $E[i][0]$, prv can be derived from nxt , twin is $i^{\wedge}1$). To make it a little faster, short-circuit the tuple comparison at (*).

Time: $\mathcal{O}(M \log M)$

WARNING: E has to contain both an edge and its reverse; moreover, the reverse of edge i has to be $i^{\wedge}1$.

5a89d3, 20 lines

vector<int> DCEL(vector<Point>& P, vector<array<int, 2>>& E) { int n = P.size(), m = E.size(); vector<int> ord(m); iota(ord.begin(), ord.end(), 0); stable_sort(ord.begin(), ord.end(), [&](int a, int b) { Point p = P[E[a][1]] - P[E[a][0]], q = P[E[b][1]] - P[E[b][0]]; return make_tuple(E[a][0], half(p), 0) // (*) > make_tuple(E[b][0], half(q), cross(p, q)); })); int l = 0, r = 0; vector<int> nxt(m); for (l = 0; l < m; l = r) { for (r = l + 1; r < m && E[ord[r]][0] == E[ord[l]][0]; ++r) nxt[ord[r - 1]] = ord[r]; nxt[ord[r - 1]] = ord[l]; }

for (int i = 0; i < m; i += 2) swap(nxt[i], nxt[i ^ 1]);

return nxt;

}

ClosestPair.h

Description: Finds the closest pair of points. Returns the minimum squared distance, along with the points. Need to include proper operator< in namespace std (see Point.h).

Usage: auto [d, p, q] = ClosestPair(pts);

Time: $\mathcal{O}(N \log N)$

"Point.h"	cc6b36, 18 lines
tuple<long long, Point, Point> ClosestPair(vector<Point> v) { assert((int)v.size() > 1); sort(v.begin(), v.end(), [&](Point a, Point b) { return a.imag() < b.imag(); }); set<Point> s; int j = 0; tuple<long long, Point, Point> ret{4e18, {}, {}}; for (auto p : v) { long long d = 1 + sqrt(get<0>(ret)); while (v[j].imag() <= p.imag() - d) s.erase(v[j++]); auto lo = s.lower_bound(p - d), hi = s.upper_bound(p + d); for (auto it = lo; it != hi; ++it) ret = min(ret, {norm(*it - p), *it, p}); s.insert(p); } return ret; }	

DynamicHull.h

Description: Dynamic convex hull tree. Useful for onion peeling. Can be made persistent by replacing the condition at (*) with true. Hull is trigonometric ordered and non-strict. To make it strict, play with the inequalities. To allow insertions as well, wrap it in a segment tree of integers and combine with the given function. Works in around 1.5 seconds for N = 200000. Does products up to $\mathcal{O}(X^3)$.

Time: $\mathcal{O}(\log^2 N)$ per operation

WARNING: *P* has to be sorted (either increasing or decreasing)

struct DynHull { struct Node { int bl, br, l, r, lc, rc; }; vector<Node> T = {{-1, -1, -1, -1, 0, 0}}; vector<Point> P; DynHull(vector<Point> P) : P(P) {} bool leaf(int x) { return T[x].l == T[x].r; } int combine(int lc, int rc, int ret = -1) { if (!lc !rc) return lc + rc; if (ret == -1 ret == lc ret == rc) // (*) ret = T.size(), T.push_back({}); T[ret] = {-1, -1, T[lc].l, T[rc].r, lc, rc}; while (!leaf(lc) !leaf(rc)) { int a = T[lc].bl, b = T[lc].br, c = T[rc].bl, d = T[rc].br; if (a != b && det(P[a], P[b], P[c]) > 0) { lc = T[lc].lc; } else if (c != d && det(P[b], P[c], P[d]) > 0) { rc = T[rc].rc; } else if (a == b) { rc = T[rc].lc; } else if (c == d) { lc = T[lc].rc; } else { auto s1 = det(P[a], P[b], P[c]), s2 = det(P[a], P[b], P[d]); assert(s1 >= s2); auto xc = P[c].real(), xd = P[d].real(), xm = P[T[rc].l].real(), xa = P[a].real(); if ((s1 * xd - s2 * xc < (s1 - s2) * xm) ^ (xa < xm)) { rc = T[rc].lc; } } } } };	cbaa78, 74 lines

            auto [a, b, c] = f;
            if (det(P[a], P[b], P[c], P[i]) > 0) // consider sgn()
                dead[a][b] = dead[b][c] = dead[c][a] = true;
            else nret.push_back(f);
        }
        ret.clear();
        for (auto f : nret) {
            ret.push_back(f);
            for (int j = 0, k = 2; j < 3; k = j++) {
                int a = f[k], b = f[j];
                if (dead[b][a]) ret.push_back({b, a, i});
                dead[b][a] = false;
            }
        }
    }
    return ret;
}
```

PolyVolume3D.h
Description: Computes the (signed) volume of a polyhedron. Faces should point outwards.

```
T Volume(vector<Point> v, vector<Face> faces) {
    double ret = 0; Point O{0, 0, 0}; // origin
    for (auto [a, b, c] : faces) ret += det(v[c], v[b], v[a], O);
    return ret / 6;
}
```

8.6 Math

8.6.1 Pick’s Theorem

If a polygon has vertices on integer coordinates, then:

$$A = I + B/2 - 1$$

where A is the polygon area, B is the number of boundary points (on vertices + edges), and I is the number of interior points (strict).

8.6.2 Euler’s Formula

If a finite, planar graph is drawn in the plane without any edge intersections, and V is the number of vertices, E is the number of edges and F is the number of faces (regions bounded by edges, including the outer, infinitely large region), then:

$$V - E + F = 2$$

$$E \leq 3V - 6$$

A more general formula for K connected components is:

$$V - E + F = 1 + K$$

Strings (9)

KMP.h
Description: $pi[x]$ is the length of the longest prefix of s that ends at x (exclusively), other than $s[0..x]$ itself. This is used by Match() to find all occurrences of a string.
Usage: ComputePi("alabala") => {-1, 0, 0, 1, 0, 1, 2, 3}
Match("atoat", "atoatoat") => {4, 7}
Time: $\mathcal{O}(N)$

```
vector<int> ComputePi(string s) {
    int n = s.size();
    vector<int> pi(n + 1, -1);
    for (int i = 0; i < n; ++i) {
        int j = pi[i];
        while (j != -1 && s[j] != s[i]) j = pi[j];
        pi[i + 1] = j + 1;
    }
    return pi;
}

vector<int> Match(string text, string pat) {
    vector<int> pi = ComputePi(pat), ret;
    for (int i = 0, j = 0; i < (int)text.size(); ++i) {
        while (j != -1 && pat[j] != text[i]) j = pi[j];
        if (++j == (int)pat.size())
            ret.push_back(i), j = pi[j];
    }
    return ret;
}
```

ZFunction.h
Description: Given a string s , computes the length of the longest common prefix of $s[i..]$ and $s[0..]$ for each $i > 0$!!
Usage: ZFunction("abacaba") => {0, 0, 1, 0, 3, 0, 1}
Time: $\mathcal{O}(N)$

```
vector<int> ZFunction(string s) {
    int n = s.size();
    vector<int> z(n);
    for (int i = 1, l = 0, r = 0; i < n; ++i) {
        if (i <= r) z[i] = min (r - i + 1, z[i - l]);
        while (i + z[i] < n && s[z[i]] == s[i + z[i]]) ++z[i];
        if (i + z[i] - 1 > r) l = i, r = i + z[i] - 1;
    }
    return z;
}
```

MinRotation.h
Description: Finds the lexicographically smallest rotation of a string.
Usage: rotate(v.begin(), v.begin() + MinRotation(v), v.end());
Time: $\mathcal{O}(N)$

```
int MinRotation(string s) {
    int a = 0, n = s.size(); s += s;
    for (int b = 0; b < n; ++b)
        for (int i = 0; i < n; ++i) {
            if (a + i == b || s[a + i] < s[b + i]) {
                b += max(0, i - 1); break;
            }
            if (s[a + i] > s[b + i]) { a = b; break; }
        }
    return a;
}
```

AhoCorasick.h
Description: Aho-Corasick algorithm builds an automaton for multiple pattern string matching
Time: $\mathcal{O}(N \log \Sigma)$ where N is the total length

```
struct AhoCorasick {
    struct Node { int link; map<char, int> leg; };
    vector<Node> T;
    vector<int> q;
    int nodes = 1;

    AhoCorasick(int sz) : T(sz) {}

    // Adds a word to trie and returns the end node
    int Add(const string &s) {
        int node = 0;
        for (auto c : s) {
            auto &nxt = T[node].leg[c];
            if (nxt == 0) nxt = nodes++;
            node = nxt;
        }
        return node;
    }
    // Advances from a node with a character (like an automaton)
    int Go(int node, char c) {
        while (node != -1 && !T[node].leg.count(c))
            node = T[node].link;
        return (node == -1 ? 0 : T[node].leg[c]);
    }
    // Builds links
    void Build() {
        T[0].link = -1, q.push_back(0);
        for (int i = 0; i < (int)q.size(); ++i) {
            int node = q[i];
            for (auto [c, vec] : T[node].leg)
                T[vec].link = Go(T[node].link, c), q.push_back(vec);
        }
    }
};
```

SuffixAutomaton.h
Description: Builds an automaton of all the suffixes of a given string (online from left to right). To support multiple strings/trie, you can add characters in BFS order of trie and it should work.
Usage: last = 0; for (auto c : s) last = SA.Add(last, c);
Time: $\mathcal{O}(\log \Sigma)$ amortized per character added

```
struct SuffixAutomaton {
    struct Node {
        int len, link;
        map<char, int> leg; // Can use array<int, 26> instead.
    };
    vector<Node> T = {{0, -1, {}}};
    // Adds another character to the automaton.
    int Add(int last, char c) {
        int node = last, cur = T.size();
        T.push_back({T[last].len + 1, 0, {}});
        while (node != -1 && !T[node].leg[c])
            T[node].leg[c] = cur, node = T[node].link;
        if (node != -1) {
            int old = T[node].leg[c], len = T[node].len + 1;
            assert(T[cur].len >= T[old].len);
            if (T[old].len == len) {
                T[cur].link = old;
            } else {
                int clone = T.size();
                T.push_back({len, T[old].link, T[old].leg});
                T[old].link = T[cur].link = clone;
                while (node != -1 && T[node].leg[c] == old)
                    T[node].leg[c] = clone, node = T[node].link;
            }
        }
    }
};
```

```
    }
    }
    return cur;
}
};
```

Manacher.h
Description: Given a string s, computes the length of the longest palindromes centered in each position (for parity == 1) or between each pair of adjacent positions (for parity == 0).
Usage: Manacher("abacaba", 1) => {0, 1, 0, 3, 0, 1, 0}
Manacher("aabbaa", 0) => {1, 0, 3, 0, 1}
Time: $\mathcal{O}(N)$

```
vector<int> Manacher(string s, bool parity) {
    int n = s.size(), z = parity, l = 0, r = 0;
    vector<int> ret(n - !z, 0);
```

```
    for (int i = 0; i < n - !z; ++i) {
        if (i + !z < r) ret[i] = min(r - i, ret[l + r - i - !z]);
        int L = i - ret[i] + !z, R = i + ret[i];
        while (L - 1 >= 0 && R + 1 < n && s[L - 1] == s[R + 1])
            ++ret[i], --L, ++R;
        if (R > r) l = L, r = R;
    }
    return ret;
}
```

PalindromicTree.h
Description: A trie-like structure for keeping track of palindromes of a string s. It has two roots, 0 (for even palindromes) and 1 (for odd palindromes). Each node stores the length of the palindrome, the count and a link to the longest "aligned" subpalindrome. Can be made online from left to right
Time: $\mathcal{O}(N)$

```
struct Node {
    map<char, int> leg;
    int link, len, cnt = 0;
};
```

```
vector<Node> PalTree(string str) {
    vector<Node> T(str.size() + 2);
    T[1].link = T[1].len = 0;
    T[0].link = T[0].len = -1;
    int last = 0, nodes = 2;
```

```
    for (int i = 0; i < (int)str.size(); ++i) {
        char now = str[i];
        int node = last;
        while (now != str[i - T[node].len - 1])
            node = T[node].link;
        if (T[node].leg.count(now)) {
            node = T[node].leg[now];
            T[node].cnt += 1;
            last = node;
            continue;
        }
        int cur = nodes++;
        T[cur].len = T[node].len + 2;
        T[node].leg[now] = cur;
        int link = T[node].link;
        while (link != -1) {
            if (now == str[i - T[link].len - 1] &&
                T[link].leg.count(now)) {
                link = T[link].leg[now];
                break;
            }
        }
        link = T[link].link;
```

```
    }
    if (link <= 0) link = 1;
    T[cur].link = link;
    T[cur].cnt = 1;
    last = cur;
}
for (int node = nodes - 1; node > 0; --node)
    T[T[node].link].cnt += T[node].cnt;

T.resize(nodes);
return T;
}
```

Various (10)

AlphaBeta.h
Description: Uses the alpha-beta pruning method to find score values for states in games (minimax). Works faster if better states are explored first.

```
int AlphaBeta(State s, int alpha, int beta) {
    if (s.done()) return s.score();
    for (State t : s.next()) {
        alpha = max(alpha, -AlphaBeta(t, -beta, -alpha));
        if (alpha >= beta) break;
    }
    return alpha;
}
```

Hashing.h
Description: Arithmetic mod $2^{64} - 1$. 2x slower than mod 2^{64} and more code, but works on evil test data (e.g. Thue-Morse, where ABBA... and BAAB... of length 2^{10} hash the same mod 2^{64}). "typedef ull H;" instead if you think test data is random, or work mod $10^9 + 7$ if the Birthday paradox is not a problem.

```
struct H {
    typedef uint64_t ull;
    ull x; H(ull x=0) : x(x) {}
#define OP(O,A,B) H operator O(H o) { ull r = x; asm \
    (A "addq %%rdx, %0\n adcq $0,%0" : "a"(r) : B); return r; }
    OP(+, "d"(o.x)) OP(*, "mul %1\n", "r"(o.x) : "rdx")
    H operator-(H o) { return *this + ~o.x; }
    ull get() const { return x + !~x; }
    bool operator==(H o) const { return get() == o.get(); }
    bool operator<(H o) const { return get() < o.get(); }
};
```

10.1 Intervals

IntervalContainer.h
Description: Add and remove intervals from a set of disjoint intervals. Will merge the added interval with any overlapping intervals in the set when adding. Intervals are [inclusive, exclusive).
Time: $\mathcal{O}(\log N)$

```
struct IntervalContainer : map<int, int> {
    iterator AddInterval(int l, int r) {
        if (l == r) return end();
        auto it = lower_bound(l);
        while (it != end() && it->first <= r) {
            r = max(r, it->second);
            it = erase(it);
        }
        while (it != begin() && (--it)->second >= l) {
            l = min(l, it->first), r = max(r, it->second);
            it = erase(it);
        }
        return emplace(l, r).first;
    }
};
```

```
iterator FindInterval(int x) {
    auto it = upper_bound(x);
    if (it == begin() || (--it)->second <= x)
        return end();
    return it;
}
void RemoveInterval(int l, int r) {
    if (l == r) return;
    auto it = AddInterval(l, r);
    auto [l2, r2] = *it; erase(it);
    if (l != l2) emplace(l2, l);
    if (r != r2) emplace(r, r2);
}
};
```

ConstantIntervals.h
Description: Split a monoene function on [b, e) into a minimal set of half-open intervals on which it has the same value. Runs a callback cb for each such interval.
Usage: ConstantIntervals(0, v.size(), [&](int x){return v[x];}, [&](int lo, int hi, T val){...});
Time: $\mathcal{O}(k \log \frac{n}{k})$

```
template<class Func, class Callback, class T>
void recurse(int b, int e, Func&& f, Callback&& cb,
             int& i, T& p, T q) {
    if (p == q) return;
    if (b == e) {
        cb(i, e, p);
        i = e; p = q;
    } else {
        int m = (b + e) / 2;
        recurse(b, m, f, cb, i, p, f(m));
        recurse(m + 1, e, f, cb, i, p, q);
    }
}
template<class Func, class Callback>
void ConstantIntervals(int b, int e, Func f, Callback cb) {
    if (e <= b) return;
    int i = b; auto p = f(i), q = f(e - 1);
    recurse(b, e - 1, f, cb, i, p, q);
    cb(i, e, q);
}
```

10.2 Dynamic programming

KnuthDP.h
Description: When doing DP on intervals: $a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i, j)$, where the (minimal) optimal k increases with both i and j , one can solve intervals in increasing order of length, and search $k = p[i][j]$ for $a[i][j]$ only between $p[i][j - 1]$ and $p[i + 1][j]$. This is known as Knuth DP. Sufficient criteria for this are if $f(b, c) \leq f(a, d)$ and $f(a, c) + f(b, d) \leq f(a, d) + f(b, c)$ for all $a \leq b \leq c \leq d$. Consider also: LineContainer (ch. Data structures), monotone queues, ternary search.
Time: $\mathcal{O}(N^2)$

10.3 Debugging tricks

- signal(SIGSEGV, [](int) { _Exit(0); }); converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG failures generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- feenableexcept(29); kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.4 Optimization tricks

`__builtin_ia32_ldmxcsr(40896);` disables denormals (which make floats 20x slower near their minimum value).

10.4.1 Bit hacks

- `x & -x` is the least bit in `x`.
- `for (int x = m; x;) { --x &= m; ... }` loops over all subset masks of `m` (except `m` itself).
- `c = x&-x, r = x+c; (((r^x) >> 2)/c) | r` is the next number after `x` with the same number of bits set.
- `rep(b,0,K) rep(i,0,(1 << K)) if (i & 1 << b) D[i] += D[i^(1 << b)];` computes all sums of subsets.

10.4.2 Pragmas

- `#pragma GCC optimize ("Ofast")` will make GCC auto-vectorize loops and optimizes floating points better.
- `#pragma GCC target ("avx2")` can double performance of vectorized code, but causes crashes on old machines.
- `#pragma GCC optimize ("trapv")` kills the program on integer overflows (but is really slow).

Montgomery.h

Description: Faster `ModInt` multiplication using Montgomery space. Copy other operators from "ModInt.h" if needed.
WARNING: Using the `ModInt` wrapper might make the operations slower. Refactor at your own risk.

```
// Set T2 such that (T2)mod * mod does not overflow.
using T = uint32_t;
using T2 = uint64_t;
const int BITS = 8 * sizeof(T); // = 32
const T MOD = 998244353, INV = 3296722945, R2 = 932051910;
//      970592641      905457281      670047489
//      1000000007      2068349879      582344008
//      3006703054056749 11535267960557300389 886200325609766
// 10000000000000000003 14584756025394899627 527506668952824130

T reduce(T2 x) {
    T q = (T)x * INV, a = (x - (T2)q * MOD) >> BITS;
    if (a >= MOD) a += MOD; // not a mistake
    return a;
}

T mul(T a, T b) { return reduce((T2)a * b); }
// Only required for unknown modulo. Call before everything.
void init(T mod) {
    MOD = mod; INV = 1; R2 = -mod % mod;
    for (int i = 1; i < BITS; i *= 2)
        INV *= 2 - MOD * INV;
    for (int i = 0; i < 4; i++)
        if ((R2 *= 2) >= mod)

    if (x >= MOD) x -= MOD;
    ModInt ret(*this); ret.x = x; return ret;
}

ModInt operator+(ModInt oth) { return ctr(x + oth.x); }
ModInt operator-(ModInt oth) { return ctr(x + MOD - oth.x); }
ModInt operator*(ModInt oth) { return ctr(mul(x, oth.x)); }
T Get() { return reduce(x); }
};
```

FastInput.h

Description: Read an integer from `stdin`. Usage requires your program to pipe in input from file.
Usage: `./a.out < input.txt`
Time: About 5x as fast as `cin/scanf`.

```
7b3c70, 17 lines
inline char gc() { // like getchar()
    static char buf[1 << 16];
    static size_t bc, be;
    if (bc >= be) {
        buf[0] = 0, bc = 0;
        be = fread(buf, 1, sizeof(buf), stdin);
    }
    return buf[bc++]; // returns 0 on EOF
}

int readInt() {
    int a, c;
    while ((a = gc()) < 40);
    if (a == '-') return -readInt();
    while ((c = gc()) >= 48) a = a * 10 + c - 480;
    return a - 48;
}
```
