Pre-submit: Write a few simple test cases if sample is not enoug Are time limits close? If so, generate max cases. Is the memory usage fine? Could anything overflow? Make sure to submit the right file.	h.					
Wrong answer: Print your solution! Print debug output, as well. Are you clearing all data structures between test ca Can your algorithm handle the whole range of input? Read the full problem statement again. Do you handle all corner cases correctly? Have you understood the problem correctly? Any uninitialized variables? Any overflows?	ses?					

onfusing N and M, i and j, etc.? re you sure your algorithm works? hat special cases have you not thought of? re you sure the STL functions you use work as you think? dd some assertions, maybe resubmit. reate some testcases to run your algorithm on. o through the algorithm for a simple case. o through this list again. xplain your algorithm to a teammate. sk the teammate to look at vour code. o for a small walk, e.g. to the toilet. s your output format correct? (including whitespace) ewrite your solution from the start or let a teammate do it. untime error: ave you tested all corner cases locally? ny uninitialized variables? re you reading or writing outside the range of any vector? ny assertions that might fail? ny possible division by 0? (mod 0 for example) ny possible infinite recursion? nvalidated pointers or iterators? re you using too much memory? ebug with resubmits (e.g. remapped signals, see Various).

ime limit exceeded: you have any possible infinite loops? hat is the complexity of your algorithm? re you copying a lot of unnecessary data? (References) ow big is the input and output? (consider scanf) void vector, map. (use arrays/unordered_map) hat do your teammates think about your algorithm?

emory limit exceeded: hat is the max amount of memory your algorithm should need? re you clearing all data structures between test cases?

Mathematics (2)

2.1 Equations

$$ax^2 + bx + c = 0 \Rightarrow x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The extremum is given by x = -b/2a.

$$ax + by = e$$

$$cx + dy = f$$

$$\Rightarrow x = \frac{ed - bf}{ad - bc}$$

$$y = \frac{af - ec}{ad - bc}$$

a general, given an equation Ax = b, the solution to a variable $_i$ is given by

$$x_i = \frac{\det A_i'}{\det A}$$

where A'_i is A with the i'th column replaced by b.

Trigonometry

$$\sin(v + w) = \sin v \cos w + \cos v \sin w$$
$$\cos(v + w) = \cos v \cos w - \sin v \sin w$$

$$\tan(v+w) = \frac{\tan v + \tan w}{1 - \tan v \tan w}$$
$$\sin v + \sin w = 2\sin\frac{v+w}{2}\cos\frac{v-w}{2}$$
$$\cos v + \cos w = 2\cos\frac{v+w}{2}\cos\frac{v-w}{2}$$

$$(V+W)\tan(v-w)/2 = (V-W)\tan(v+w)/2$$

where V, W are lengths of sides opposite angles v, w.

$$a\cos x + b\sin x = r\cos(x - \phi)$$
$$a\sin x + b\cos x = r\sin(x + \phi)$$

where $r = \sqrt{a^2 + b^2}$, $\phi = \operatorname{atan2}(b, a)$.

2.3 Algebra

Let $H \subseteq \mathbb{Z}_n$ non-empty subset. H is subgroup iff exists d divisor of n such that $H = \hat{d}\mathbb{Z}_n$.

Geometry

2.4.1 Triangles

Side lengths: a, b, c

Semiperimeter:
$$p = \frac{a+b+c}{2}$$

Area: $A = \sqrt{p(p-a)(p-b)(p-c)}$

Circumradius: $R = \frac{abc}{4A}$

Inradius: $r = \frac{A}{}$

Length of median (divides triangle into two equal-area triangles):

 $m_a = \frac{1}{2}\sqrt{2b^2 + 2c^2 - a^2}$

Length of bisector (divides angles in two):

$$s_a = \sqrt{bc \left[1 - \left(\frac{a}{b+c} \right)^2 \right]}$$

Law of sines: $\frac{\sin \alpha}{a} = \frac{\sin \beta}{b} = \frac{\sin \gamma}{c} = \frac{1}{2R}$ Law of cosines: $a^2 = b^2 + c^2 - 2bc \cos \alpha$

Law of tangents: $\frac{a+b}{a-b} = \frac{\tan \frac{\alpha+\beta}{2}}{\tan \frac{\alpha-\beta}{2}}$

2.4.2 Quadrilaterals

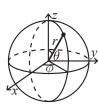

With side lengths a, b, c, d, diagonals e, f, diagonals angle θ , area A and magic flux $F = b^2 + d^2 - a^2 - c^2$:

$$4A = 2ef \cdot \sin \theta = F \tan \theta = \sqrt{4e^2 f^2 - F^2}$$

For cyclic quadrilaterals the sum of opposite angles is 180°, ef = ac + bd, and $A = \sqrt{(p-a)(p-b)(p-c)(p-d)}$

.bashrc .vimrc hash troubleshoot

2.4.3 Spherical coordinates

$$x = r \sin \theta \cos \phi \qquad r = \sqrt{x^2 + y^2 + z^2}$$

$$y = r \sin \theta \sin \phi \qquad \theta = a\cos(z/\sqrt{x^2 + y^2 + z^2})$$

$$z = r \cos \theta \qquad \phi = a\tan(y, x)$$

2.5 Derivatives/Integrals

$$\frac{d}{dx}\arcsin x = \frac{1}{\sqrt{1-x^2}} \qquad \frac{d}{dx}\arccos x = -\frac{1}{\sqrt{1-x^2}}$$

$$\frac{d}{dx}\tan x = 1 + \tan^2 x \qquad \frac{d}{dx}\arctan x = \frac{1}{1+x^2}$$

$$\int \tan ax = -\frac{\ln|\cos ax|}{a} \qquad \int x\sin ax = \frac{\sin ax - ax\cos ax}{a^2}$$

$$\int e^{-x^2} = \frac{\sqrt{\pi}}{2}\operatorname{erf}(x) \qquad \int xe^{ax}dx = \frac{e^{ax}}{a^2}(ax-1)$$

Integration by parts

$$\int_{a}^{b} f(x)g(x)dx = [F(x)g(x)]_{a}^{b} - \int_{a}^{b} F(x)g'(x)dx$$

Beta Function

$$B(x,y) = n \int_0^1 t^{nx-1} (1 - t^n)^{y-1} dt$$

$$B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}$$

$$B(x,y) = B(x,y+1) + B(x+1,y)$$

$$B(x+1,y) = B(x,y) \frac{x}{x+y}$$

$$B(x,y) = B(y,x)$$

$$B(1,x) = \frac{1}{x}$$

$$B(x;a,b) = \int_0^x t^{a-1} (1-t)^{b-1} dt$$

$$B(1;a,b) = B(a,b)$$

$$I_x(a,b) = \frac{B(x;a,b)}{B(a,b)}$$

$$I_0(a,b) = 0 \qquad I_1(a,b) = 1 \qquad I_x(a,1) = x^a$$

$$I_x(1,b) = 1 - (1-x)^b \qquad I_x(a,b) = 1 - I_{1-x}(b,a)$$

$$I_x(a+1,b) = I_x(a,b) - \frac{x^a(1-x)^b}{aB(a,b)}$$

$$I_x(a,b+1) = I_x(a,b) + \frac{x^a(1-x)^b}{bB(a,b)}$$

Gamma Function

$$\Gamma(n) = (n-1)!$$

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$$

$$\Gamma(1/2) = \sqrt{\pi}$$

$$\Gamma(z+1) = z\Gamma(z)$$

2.6 Sums

$$c^{a} + c^{a+1} + \dots + c^{b} = \frac{c^{b+1} - c^{a}}{c - 1}, c \neq 1$$

$$1 + 2 + 3 + \dots + n = \frac{n(n+1)}{2}$$

$$1^{2} + 2^{2} + 3^{2} + \dots + n^{2} = \frac{n(2n+1)(n+1)}{6}$$

$$1^{3} + 2^{3} + 3^{3} + \dots + n^{3} = \frac{n^{2}(n+1)^{2}}{4}$$

$$1^{4} + 2^{4} + 3^{4} + \dots + n^{4} = \frac{n(n+1)(2n+1)(3n^{2} + 3n - 1)}{30}$$

2.7 Series

$$e^{x} = 1 + x + \frac{x^{2}}{2!} + \frac{x^{3}}{3!} + \dots, (-\infty < x < \infty)$$

$$\ln(1+x) = x - \frac{x^{2}}{2} + \frac{x^{3}}{3} - \frac{x^{4}}{4} + \dots, (-1 < x \le 1)$$

$$\sqrt{1+x} = 1 + \frac{x}{2} - \frac{x^{2}}{8} + \frac{2x^{3}}{32} - \frac{5x^{4}}{128} + \dots, (-1 \le x \le 1)$$

$$\sin x = x - \frac{x^{3}}{3!} + \frac{x^{5}}{5!} - \frac{x^{7}}{7!} + \dots, (-\infty < x < \infty)$$

$$\cos x = 1 - \frac{x^{2}}{2!} + \frac{x^{4}}{4!} - \frac{x^{6}}{6!} + \dots, (-\infty < x < \infty)$$

2.8 Probability theory

Let X be a discrete random variable with probability $p_X(x)$ of assuming the value x. It will then have an expected value (mean) $\mu = \mathbb{E}(X) = \sum_x x p_X(x)$ and variance $\sigma^2 = V(X) = \mathbb{E}(X^2) - (\mathbb{E}(X))^2 = \sum_x (x - \mathbb{E}(X))^2 p_X(x)$ where σ is the standard deviation. If X is instead continuous it will have a probability density function $f_X(x)$ and the sums above will instead be integrals with $p_X(x)$ replaced by $f_X(x)$.

Expectation is linear:

$$\mathbb{E}(aX + bY) = a\mathbb{E}(X) + b\mathbb{E}(Y)$$

For independent X and Y,

$$V(aX + bY) = a^2V(X) + b^2V(Y).$$

2.8.1 Discrete distributions Binomial distribution

The number of successes in n independent yes/no experiments, each which yields success with probability p is $Bin(n,p), n=1,2,\ldots,0 \le p \le 1$.

$$p(k) = \binom{n}{k} p^k (1-p)^{n-k}$$
$$u = np, \ \sigma^2 = np(1-p)$$

Bin(n, p) is approximately Po(np) for small p.

For n large enough, Bin(n, p) is approximately $\mathcal{N}(np, np(1-p))$.

Negative binomial NBin(r, p):

$$F(r+k) = 1 - I_p(k+1,r) = I_{1-p}(r,k+1) = F_{Bin}(k,k+r,p)$$

First success distribution

The number of trials needed to get the first success in independent yes/no experiments, each wich yields success with probability p is Fs(p), $0 \le p \le 1$.

$$p(k) = p(1-p)^{k-1}, k = 1, 2, ...$$

 $\mu = \frac{1}{p}, \sigma^2 = \frac{1-p}{p^2}$

Poisson distribution

The number of events occurring in a fixed period of time t if these events occur with a known average rate κ and independently of the time since the last event is $Po(\lambda)$, $\lambda = t\kappa$.

$$p(k) = e^{-\lambda} \frac{\lambda^k}{k!}, k = 0, 1, 2, \dots$$
$$\mu = \lambda, \sigma^2 = \lambda$$
$$\lambda = rt$$

OrderStatisticTree HashMap SegTree RMQ BiVec CHT

2.8.2 Continuous distributions Uniform distribution

If the probability density function is constant between a and band 0 elsewhere it is U(a, b), a < b.

$$f(x) = \begin{cases} \frac{1}{b-a} & a < x < b \\ 0 & \text{otherwise} \end{cases}$$

$$\mu = \frac{a+b}{2}, \, \sigma^2 = \frac{(b-a)^2}{12}$$

Exponential distribution

The time between events in a Poisson process is $\operatorname{Exp}(\lambda), \lambda > 0.$

$$f(x) = \begin{cases} \lambda e^{-\lambda x} & x \ge 0\\ 0 & x < 0 \end{cases}$$
$$\mu = \frac{1}{\lambda}, \, \sigma^2 = \frac{1}{\lambda^2}$$

Normal distribution

Most real random values with mean μ and variance σ^2 are well described by $\mathcal{N}(\mu, \sigma^2)$, $\sigma > 0$.

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

If $X_1 \sim \mathcal{N}(\mu_1, \sigma_1^2)$ and $X_2 \sim \mathcal{N}(\mu_2, \sigma_2^2)$ then

$$aX_1 + bX_2 + c \sim \mathcal{N}(\mu_1 + \mu_2 + c, a^2\sigma_1^2 + b^2\sigma_2^2)$$

2.9 Markov chains

A Markov chain is a discrete random process with the property that the next state depends only on the current state. Let X_1, X_2, \dots be a sequence of random variables generated by the Markov process. Then there is a transition matrix $\mathbf{P} = (p_{ij})$, with $p_{ij} = \Pr(X_n = i | X_{n-1} = j)$, and $\mathbf{p}^{(n)} = \mathbf{P}^n \mathbf{p}^{(0)}$ is the probability distribution for X_n (i.e., $p_i^{(n)} = \Pr(X_n = i)$), where $\mathbf{p}^{(0)}$ is the initial distribution.

 π is a stationary distribution if $\pi = \pi \mathbf{P}$. If the Markov chain is irreducible (it is possible to get to any state from any state), then $\pi_i = \frac{1}{\mathbb{E}(T_i)}$ where $\mathbb{E}(T_i)$ is the expected time between two visits in state i. π_i/π_i is the expected number of visits in state j between two visits in state i.

For a connected, undirected and non-bipartite graph, where the transition probability is uniform among all neighbors, π_i is proportional to node i's degree.

A Markov chain is *ergodic* if the asymptotic distribution is independent of the initial distribution. A finite Markov chain is ergodic iff it is irreducible and aperiodic (i.e., the gcd of cycle lengths is 1). $\lim_{k\to\infty} \mathbf{P}^k = \mathbf{1}\pi$.

A Markov chain is an A-chain if the states can be partitioned into two sets A and G, such that all states in A are absorbing $(p_{ii}=1)$, and all states in **G** leads to an absorbing state in **A**. The probability for absorption in state $i \in \mathbf{A}$, when the initial state is j, is $a_{ij} = p_{ij} + \sum_{k \in \mathbf{G}} a_{ik} p_{kj}$. The expected time until absorption, when the initial state is i, is $t_i = 1 + \sum_{k \in C} p_{ki} t_k$.

Data structures (3)

OrderStatisticTree.h

Description: A set (not multiset!) with support for finding the n^{th} element, and finding the index of an element. To get a map, change null type. Time: $\mathcal{O}(\log N)$

```
#include <bits/extc++.h>
using namespace __gnu_pbds;
template <class T>
using Tree = tree<T, null_type, less<T>, rb_tree_tag,
   tree_order_statistics_node_update>;
void example() {
 Tree<int> T, T2; T.insert(8);
 auto it = T.insert(10).first;
 assert(it == T.lower_bound(9));
 assert(T.order_of_key(10) == 1);
 assert(T.order of key(11) == 2);
 assert(*T.find_by_order(0) == 8);
 T.join(T2); // assuming T < T2 or T > T2, merge T2 into T
```

HashMap.h

Description: Hash map with mostly the same API as unordered map, but ~3x faster. Uses 1.5x memory. Initial capacity must be a power of 2 (if provided).

```
#include <bits/extc++.h>
// To use most bits rather than just the lowest ones:
struct chash { // large odd number for C
 static const uint64_t C = ll(4e18 * acos(0)) | 71;
 ll operator()(ll x) const { return __builtin_bswap64(x*C); }
__gnu_pbds::gp_hash_table<ll,int,chash> H({},{},{},{},{1<<16});
```

SegTree.h

Description: Very fast and quick segment tree. Only useful for easy invariants. 0-indexed. Range queries are half-open. 39c971, 17 lines

```
struct SegTree {
 vector<ll> T; int n;
 SegTree(int n) : T(2 * n, -INF), n(n) {}
 void Update(int pos, ll val) {
   for (T[pos += n] = val; pos /= 2)
     T[pos] = f(T[pos * 2], T[pos * 2 + 1]);
 ll Query(int b, int e) {
   ll r1 = -INF, r2 = -INF;
   for (b += n, e += n; b < e; b /= 2, e /= 2) {
     if (b % 2) r1 = max(r1, T[b++]);
     if (e % 2) r2 = max(T[--e], r2);
   return max(r1, r2);
```

```
RMQ.h
Description: Disjoint Sparse Table implementation. Returns \min_{i=1}^{r-1} v[i] in
constant time. Can be adapted for other things, like sum or product.
Usage: RMO rmg(values):
rmq.Query(inclusive, exclusive);
Time: \mathcal{O}(N \log N + Q)
                                                        08a630, 20 lines
struct RMO {
 vector<int> dp[32];
  RMQ(const vector<int> &v) {
    int n = v.size();
    for (int h = 0, l = 1; l <= n; ++h, l *= 2) {
      dp[h].resize(n + 1, 1e9);
      for (int m = 1; m < n + 1; m += 2 * 1) {
        for (int i = m + 1; i <= min(n, m + l); i++)</pre>
          dp[h][i] = min(dp[h][i - 1], v[i - 1]);
        for (int i = min(n, m) - 1; i >= m - l; i--)
          dp[h][i] = min(v[i], dp[h][i + 1]);
  int Query(int l, int r) {
    int h = 31 - __builtin_clz(l ^ r);
    return min(dp[h][l], dp[h][r]);
};
BiVec.h
Description: Bi-directional vector (indices in [-n..n)).
```

adce61, 7 lines

```
template<typename T>
struct BiVec {
  vector<T> v;
  BiVec(int n, T x = \{\}) : v(2 * n, x) \{\}
  T& operator[](int i) { return v[2 * max(i, \sim i) + (i < 0)]; }
  void resize(int n) { v.resize(2 * n); }
```

CHT.h

Description: Simple convex hull trick. Requires lines to be inserted in increasing slopes order. Queries have to be increasing in x, but it can be relaxed to any values, by doing binary search on the stack.

Time: $\mathcal{O}(1)$ amortized per operation ae84bc, 23 lines

```
struct CHT {
 deque<tuple<ll. ll. ll>> stk:
 ll ceil(ll a, ll b) { return a / b + (a % b > 0); }
 void InsertLine(ll a, ll b) {
   ll p = -INF;
   while (stk.size()) {
     auto [pp, ap, bp] = stk.back();
     if (ap == a) p = bp > b ? INF : -INF;
     else p = ceil(bp - b, a - ap);
     if (p > pp) break;
     stk.pop_back();
   if (p != INF) stk.emplace_back(p, a, b);
 ll EvalMax(ll x) {
    // prev(upper bound(all(stk), \{x, INF, INF\}))
   while ((int)stk.size() > 1 && get<0>(stk[1]) <= x)</pre>
     stk.pop_front();
   auto [_, a, b] = stk.front();
   return a * x + b;
```

LineContainer.h

};

Description: Container where you can add lines of the form kx+m, and query maximum values at points x. Useful for dynamic programming ("convex hull trick").

Time: $\mathcal{O}(\log N)$ amortized per operation

de3210, 33 lines

```
using ll = long long;
const ll INF = 1e18;
bool QUERY;
struct Line {
  mutable ll a, b, p;
  ll Eval(ll x) const { return a * x + b; }
  bool operator<(const Line& o) const {</pre>
    return QUERY ? p < o.p : a < o.a;</pre>
struct LineContainer : multiset<Line> {
  ll div(ll a, ll b) { return a / b - (a % b < 0); }</pre>
  void InsertLine(ll a, ll b) {
    auto isect = [&](auto x, auto y) {
      if (y == end()) return x->p = INF, false;
      if (x->a == y->a) x->p = x->b > y->b ? INF : -INF;
      else x->p = div(x->b - y->b, y->a - x->a);
      return x->p >= y->p:
    auto nx = insert({a, b, 0}), it = nx++, pv = it;
    while (isect(it, nx)) nx = erase(nx);

     isect(pv, it = erase(it));
    while ((it = pv) != begin() && (--pv)->p >= it->p)
      isect(pv, erase(it));
  ll EvalMax(ll x) {
    assert(!empty());
    QUERY = 1; auto it = lower_bound(\{0, 0, x\}); QUERY = 0;
    return it->Eval(x);
};
```

ConvexTree.h

Description: Container where you can add lines of the form $a \cdot X + b$, and query maximum values at points x. Useful for dynamic programming. To change to minimum, either change the sign of all comparisons, or just add lines of form $(-a) \cdot X + (-b)$ instead and negate the result.

Time: $\mathcal{O}(\log MAX)$ per operation

1969de, 39 lines

```
struct Line { ll a, b; };
struct ConvexTree {
  struct Node { int dp; int l = -1, r = -1; };
 vector<Node> T; vector<Line> L;
 const int MAX = 1e9; //>= abs(x) for all queries.
 int root = -1:
 ll eval(int i, int x) { return L[i].a * x + L[i].b; }
  int update(int node, int b, int e, int upd) {
   if (node == -1) {
     T.push_back({upd});
     return T.size() - 1;
    int& cur = T[node].dp;
   int m = (b + e) / 2;
    int l = T[node].l, r = T[node].r;
   bool bb = eval(upd, b) > eval(cur, b);
   bool bm = eval(upd, m) > eval(cur, m);
   if (bm) swap(cur, upd);
```

```
if (e - b == 1) { /* do nothing */ }
  else if (bb != bm) l = update(l, b, m, upd);
  else r = update(r, m, e, upd);
  T[node].l = l; T[node].r = r;
  return node;
}
ll query(int node, int b, int e, int x) {
  if (node == -1) return -INF; // <= a * x + b for all lines.
  int m = (b + e) / 2;
  return max(eval(T[node].dp, x), (x <= m
    ? query(T[node].l, b, m, x)
    : query(T[node].r, m + 1, e, x)));
}
void Update(Line l) {
    L.push_back(l);
    root = update(root, -MAX, MAX, L.size() - 1);
}
ll Query(int x) { return query(root, -MAX, MAX, x); }
};</pre>
```

KinTour.h

Description: Kinetic tournament data structure. Allows updates of type modify function $f_i(\cdot)$ and query maximum of $f_i(t)$. Queries have to be increasing in t. Modify at will. Useful for temporal sweeps.

Time: Approx $\mathcal{O}\left(\log^2 N\right)$ amortized per operation.

c25240, 36 lines

```

  return recurse(f, a, b, eps, simpson(f, a, b));
```

4.2 Optimization

Simplex.h

Description: Solves a general linear maximization problem: maximize c^Tx subject to $Ax \leq b$, $x \geq 0$. Returns -INF if there is no solution, INF if there are arbitrarily good solutions, or the maximum value of c^Tx otherwise. The input vector is set to an optimal x (or in the unbounded case, an arbitrary solution fulfilling the constraints). Numerical stability is not guaranteed. For better performance, define variables such that x = 0 is viable. **Usage:** $A = \{\{1, -1\}, \{-1, 1\}, \{-1, -2\}\};$

```
\begin{array}{lll} \texttt{b} = \{1,1,-4\}, & \texttt{c} = \{-1,-1\}, & \texttt{x}; \\ \texttt{T} & \texttt{val} = \texttt{LPSolver}(\texttt{A}, \texttt{b}, \texttt{c}). \\ \texttt{Solve}(\texttt{x}); \\ \textbf{Time:} & \mathcal{O}(NM*\#pivots), \text{ where a pivot may be e.g. an edge relaxation.} \\ \mathcal{O}(2^n) & \text{ in the general case.} & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & &

```

4.2.1 LP dualization

To dualize a LP, add one dual variable for each primal constraint. Function to optimize becomes b^Ty . Then, you have one dual constraint for each primal variable, given by the primal constraints in which they appear. If primal is not unbounded nor infeasible, then neither the dual is, and strong duality holds (i.e., $c^Tx^*=b^Ty^*$).

```
\begin{array}{|c|c|c|} \hline \textbf{Primal} & \textbf{Dual} \\ \hline \max c^T x \text{ s.t. } Ax \leq b, x \geq 0 & \min b^T y \text{ s.t. } A^T y \geq c, y \geq 0 \\ \max c^T x \text{ s.t. } Ax \leq b & \min b^T y \text{ s.t. } A^T y = c, y \geq 0 \\ \max c^T x \text{ s.t. } Ax = b, x \geq 0 & \min b^T y \text{ s.t. } A^T y \geq c \\ \end{array}
```

4.3 Matrices

RowEchelon.h

Description: Converts matrix to reduced row-echelon form. Each of the first r rows will have exactly one non-zero column piv_i , and all columns to the left of piv_i will be zero. To compute rank, do RowEchelon(M).size(). Time: $\mathcal{O}\left(M^2N\right)$

```
using ld = double;
using mat = vector<vector<ld>>:
const ld EPS = 1e-9;
pair<vector<int>, int> RowEchelon(mat& A) {
 int n = A.size(), m = A[0].size(), sgn = 1;
  vector<int> piv;
  for (int i = 0, rnk = 0; i < m && rnk < n; ++i) {
    for (int j = rnk + 1; j < n; ++j)
      if (abs(A[j][i]) > abs(A[rnk][i]))
        swap(A[j], A[rnk]), sgn = -sgn;
    if (abs(A[rnk][i]) < EPS) continue;</pre>
    for (int j = 0; j < n; ++j) {
      ld coef = A[j][i] / A[rnk][i];
      if (j == rnk || abs(coef) < EPS) continue;</pre>
      for (int k = 0; k < m; ++k)
        A[j][k] -= coef * A[rnk][k];
    piv.push_back(i); ++rnk;
  return {piv, sgn};
```

SolveLinear.h

Description: Solves Mx = b. Set A to be the block matrix [M|b]. If there are multiple solutions, returns a sol which has all free variables set to 0. **Time:** $\mathcal{O}(M^2N)$

```
"RowEchelon.h"
vector<ld> SolveLinear(mat& A) {

    A[i].erase(A[i].begin(), A[i].begin() + n);
  return true;
```

4.3.1 Matrix determinant lemma

Suppose A is an invertible square matrix and u, v are column vectors. Then:

$$det(A + uv^{T}) = (1 + v^{T}A^{-1}u)det(A) = det(A) + v^{T}adj(A)u$$

Here, uv^T is the outer product of u and v. The first and third expressions are equal even when the square matrix A is not invertible.

4.4 Search

GoldenSectionSearch.h

Description: Finds the argument minimizing the function f in the interval [a,b] assuming f is unimodal on the interval, i.e. has only one local minimum. Works equally well for maximization with a small change in the code. See TernarySearch.h in the Various chapter for a discrete version.

Usage: double func(double x) { return 4+x+.3*x*x; } double xmin = GoldenSectionSearch(-1000.1000.func):

Time: $\mathcal{O}(\log((b-a)/\epsilon))$ 909fb9, 15 lines

```
template<typename Func>
double GoldenSectionSearch(double a, double b, Func f) {
  double r = (sqrt(5) - 1) / 2;
  double x1 = b - r * (b - a), x2 = a + r * (b - a);
  double f1 = f(x1), f2 = f(x2);
  for (int it = 0; it < 64; ++it)</pre>
   if (f1 < f2) { // change to > to find maximum
     b = x2; x2 = x1; f2 = f1;
     x1 = b - r * (b - a); f1 = f(x1);
     a = x1; x1 = x2; f1 = f2;
     x2 = a + r * (b - a); f2 = f(x2);
  return (a + b) / 2;
```

TernarySearch.h

Description: Find the smallest i in [a,b] that maximizes f(i), assuming that $f(a) < \ldots < f(i) > \cdots > f(b)$. To reverse which of the sides allows non-strict inequalities, change the < marked with (A) to <=, and reverse the loop at (B). To minimize f, change it to >, also at (B).

Usage: int ind = TernarySearch(0,n,[&](int i){return a[i];}); Time: $\mathcal{O}(\log(b-a))$ 0f6f0d, 12 lines

```
template<typename Func>
int TernarySearch(int a, int b, Func f) {
  assert(a <= b);</pre>
  while (b - a >= 5) {
   int mid = (a + b) / 2;
```

```
for (int i = a + 1; i < b; ++i)
 return a;
FracBinarySearch.h
Description: Finds the smallest fraction p/q \in [0,1] such that f(p/q) is
true, and p < maxp, q < maxq. You may want to throw an exception from
f if it finds an exact solution, in which case maxp, maxq can be removed.
Time: \mathcal{O}(\log(maxq))
using ll = long long;

     wn = wn * w;
   swap(a, b);
 if (rev) {
   auto n1 = ModInt(n).inv();
   for (auto& x : a) x = x * n1;
```

FST.h

Description: Transform to a basis with fast convolutions of the form $c[x \oplus y] += a[x] \cdot b[y]$, where \oplus is one of AND, OR, XOR. The size of a must be a power of two. Time: $\mathcal{O}(N \log N)$

```
void DFT(vector<int>& a, bool rev) {
 int n = a.size(); // assert(!(n \& (n-1)));
  for (int step = 1; step < n; step *= 2)
  for (int i = 0; i < n; i += 2 * step)</pre>
  for (int j = i; j < i + step; ++j) {</pre>
    auto u = a[j], v = a[j + step];
    tie(a[j], a[j + step]) =
      rev ? make_pair(v - u, u) : make_pair(v, u + v); // AND
      rev ? make_pair(v, u - v) : make_pair(u + v, u); // OR
      make_pair(u + v, u - v);
 if (rev) for (auto& x : a) x /= n; // XOR only
```

SubsetConv.h

Description: Neat trick to compute $c[x|y] += a[x] \cdot b[y]$, where x and y satisfy x & y = 0. Use with "OR" FST transform. The idea is to do FST convolutions and discard the results unless the number of bits of the result equals the sums of the bits of the multiplicants. The idea can probably be adapted to other similar problems.

```
Time: \mathcal{O}(N \log^2 N) (around 2s for N = 2^{20})
"FST.h"
```

IntPerm multinomial

5.3 Divisibility

5.3.1 Bézout's identity

For $a \neq b \neq 0$, then d = gcd(a, b) is the smallest positive integer for which there are integer solutions to

$$ax + by = d$$

If (x, y) is one solution, then all solutions are given by

$$\left(x + \frac{kb}{\gcd(a,b)}, y - \frac{ka}{\gcd(a,b)}\right), \quad k \in \mathbb{Z}$$

5.4 Pythagorean Triples

The Pythagorean triples are uniquely generated by

$$a = k \cdot (m^2 - n^2), b = k \cdot (2mn), c = k \cdot (m^2 + n^2),$$

with m > n > 0, k > 0, $m \perp n$, and either m or n even.

5.5 Primes

p=962592769 is such that $2^{21}\mid p-1,$ which may be useful. For hashing use 970592641 (31-bit number), 31443539979727 (45-bit), 3006703054056749 (52-bit). There are 78498 primes less than $1\,000\,000.$

Primitive roots exist modulo any prime power p^a , except for p=2,a>2, and there are $\phi(\phi(p^a))$ many. For p=2,a>2, the group $\mathbb{Z}_{2^a}^{\times}$ is instead isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_{2^{a-2}}$.

5.6 Estimates

$$\sum_{d|n} d = O(n \log \log n)$$

The number of divisors of n is at most around 100 for n < 5e4, 500 for n < 1e7, 2000 for n < 1e10, 200 000 for n < 1e19.

5.7 Mobius Function

$$\mu(n) = \begin{cases} 0 & n \text{ is not square free} \\ 1 & n \text{ has even number of prime factors} \\ -1 & n \text{ has odd number of prime factors} \end{cases}$$

Mobius Inversion:

$$g(n) = \sum_{d|n} f(d) \Leftrightarrow f(n) = \sum_{d|n} \mu(d)g(n/d)$$

Other useful formulas/forms:

$$\sum_{d|n} \mu(d) = [n=1]$$
 (very useful)

$$g(n) = \sum_{n|d} f(d) \Leftrightarrow f(n) = \sum_{n|d} \mu(d/n)g(d)$$

$$g(n) = \sum_{1 \le m \le n} f(\lfloor \frac{n}{m} \rfloor) \Leftrightarrow f(n) = \sum_{1 \le m \le n} \mu(m) g(\lfloor \frac{n}{m} \rfloor)$$

Combinatorial (6)

6.1 Permutations

6.1.1 Factorial

n	1 2 3	4	5 6	7	8	9	10	
n!	1 2 6	24 1	20 720	5040	40320	362880	3628800	
n	11	12	13	14	15	16	17	
n!	4.0e7	4.8e	8 6.2e	9 8.7e1	l0 1.3e	$12 \ 2.1e1$	3 3.6e14	
n	20	25	30	40	50 - 10	00 - 150) 171	
n!	2e18	2e25	3e32 8	8e47 3	e64 9e1	57 6e20	$32 > DBL_N$	IAX

IntPerm.h

Description: Permutation -> integer conversion. (Not order preserving.) Integer -> permutation can use a lookup table. **Time:** $\mathcal{O}(n)$

6.1.2 Cycles

Let $g_S(n)$ be the number of *n*-permutations whose cycle lengths all belong to the set S. Then

$$\sum_{n=0}^{\infty} g_S(n) \frac{x^n}{n!} = \exp\left(\sum_{n \in S} \frac{x^n}{n}\right)$$

6.1.3 Derangements

Permutations of a set such that none of the elements appear in their original position.

$$D(n) = (n-1)(D(n-1) + D(n-2)) = nD(n-1) + (-1)^n = \left\lfloor \frac{n!}{e} \right\rfloor$$

6.1.4 Burnside's lemma

Given a group G of symmetries and a set X, the number of elements of X up to symmetry equals

$$\frac{1}{|G|} \sum_{g \in G} |X^g|,$$

where X^g are the elements fixed by g (g.x = x).

If f(n) counts "configurations" (of some sort) of length n, we can ignore rotational symmetry using $G = \mathbb{Z}_n$ to get

$$g(n) = \frac{1}{n} \sum_{k=0}^{n-1} f(\gcd(n,k)) = \frac{1}{n} \sum_{k|n} f(k)\phi(n/k).$$

6.2 Partitions and subsets

6.2.1 Partition function

Number of ways of writing n as a sum of positive integers, disregarding the order of the summands.

$$p(0) = 1, \ p(n) = \sum_{k \in \mathbb{Z} \setminus \{0\}} (-1)^{k+1} p(n - k(3k - 1)/2)$$

6.2.2 Lucas' Theorem

Let n, m be non-negative integers and p a prime. Write $n = n_k p^k + ... + n_1 p + n_0$ and $m = m_k p^k + ... + m_1 p + m_0$. Then $\binom{n}{m} \equiv \prod_{i=0}^k \binom{n_i}{m_i} \pmod{p}$.

6.2.3 Binomials

multinomial.h

6.3 General purpose numbers

6.3.1 Bernoulli numbers

EGF of Bernoulli numbers is $B(t) = \frac{t}{e^t - 1}$ (FFT-able). $B[0, \ldots] = [1, -\frac{1}{2}, \frac{1}{6}, 0, -\frac{1}{30}, 0, \frac{1}{42}, \ldots]$

Sums of powers:

$$\sum_{i=1}^{n} n^{m} = \frac{1}{m+1} \sum_{k=0}^{m} {m+1 \choose k} B_{k} \cdot (n+1)^{m+1-k}$$

Euler-Maclaurin formula for infinite sums:

$$\sum_{i=m}^{\infty} f(i) = \int_{m}^{\infty} f(x)dx - \sum_{k=1}^{\infty} \frac{B_{k}}{k!} f^{(k-1)}(m)$$

$$\approx \int_{m}^{\infty} f(x)dx + \frac{f(m)}{2} - \frac{f'(m)}{12} + \frac{f'''(m)}{720} + O(f^{(5)}(m))$$

6.3.2 Stirling numbers of the first kind

Number of permutations on n items with k cycles.

$$c(n,k) = c(n-1,k-1) + (n-1)c(n-1,k), \ c(0,0) = 1$$

$$\sum_{k=0}^{n} c(n,k)x^{k} = x(x+1)\dots(x+n-1)$$

c(8,k) = 8,0,5040,13068,13132,6769,1960,322,28,1c(n,2) = 0,0,1,3,11,50,274,1764,13068,109584,...

6.3.3 Eulerian numbers

Number of permutations $\pi \in S_n$ in which exactly k elements are greater than the previous element. k j:s s.t. $\pi(j) > \pi(j+1)$, k+1 j:s s.t. $\pi(j) > j$, k j:s s.t. $\pi(j) > j$.

$$E(n,k) = (n-k)E(n-1,k-1) + (k+1)E(n-1,k)$$

$$E(n,0) = E(n,n-1) = 1$$

$$E(n,k) = \sum_{j=0}^{k} (-1)^{j} \binom{n+1}{j} (k+1-j)^{n}$$

6.3.4 Stirling numbers of the second kind

Partitions of n distinct elements into exactly k groups.

$$S(n,k) = S(n-1,k-1) + kS(n-1,k)$$

$$S(n,1) = S(n,n) = 1$$

$$S(n,k) = \frac{1}{k!} \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} j^{n}$$

6.3.5 Bell numbers

Total number of partitions of n distinct elements. B(n) = $1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147, \ldots$ For p prime.

$$B(p^m + n) \equiv mB(n) + B(n+1) \pmod{p}$$

6.3.6 Labeled unrooted trees

on n vertices: n^{n-2} # on k existing trees of size n_i : $n_1 n_2 \cdots n_k n^{k-2}$ # with degrees d_i : $(n-2)!/((d_1-1)!\cdots(d_n-1)!)$

6.3.7 Catalan numbers

$$C_n = \frac{1}{n+1} {2n \choose n} = {2n \choose n} - {2n \choose n+1} = \frac{(2n)!}{(n+1)!n!}$$

$$C_0 = 1, \ C_{n+1} = \frac{2(2n+1)}{n+2} C_n, \ C_{n+1} = \sum_{i=1}^{n} C_i C_{n-i}$$

 $C_n = 1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862, 16796, 58786, \dots$

- sub-diagonal monotone paths in an $n \times n$ grid.
- strings with n pairs of parenthesis, correctly nested.
- binary trees with with n+1 leaves (0 or 2 children).
- ordered trees with n+1 vertices.
- ways a convex polygon with n+2 sides can be cut into triangles by connecting vertices with straight lines.
- \bullet permutations of [n] with no 3-term increasing subseq.

Number of bracket sequences of length 2n that begin with k open brackets: $\frac{k+1}{n+1}\binom{2n-k}{n-k}$

Number of ways n + m open and n - m close brackets can be arranged to form a start of a valid bracket sequence:

6.3.8 Narayana numbers

$$N(n,k) = \frac{1}{n} \binom{n}{k} \binom{n}{k-1}$$

- bracket sequences of length 2n that consist of k "blocks" (i.e. there are k prefixes that are balanced).
- \bullet unlabeled rooted trees with n edges and k leaves

Graph (7)

7.1 General

SCC.h

Description: Finds strongly connected components in a directed graph. If vertices u, v belong to the same component, we can reach u from v and vice

Usage: SCC(graph, [&](auto& v) $\{ \dots \}$) visits all components in reverse topological order. Time: $\mathcal{O}\left(E+V\right)$

1deb0c, 22 lines

```
template<class CB>
void SCC(vector<vector<int>>& graph, CB cb) {
 int n = graph.size(), timer = 0;
 vector<int> val(n, 0), stk, cont;
 function<int(int)> dfs = [&](int node) {
   int low: low = val[node] = ++timer:
   int sz = stk.size(); stk.push_back(node);
    for (auto vec : graph[node])
       if (val[vec] != -1)
         low = min(low, val[vec] ?: dfs(vec));
   if (low == val[node]) {
      cont = {stk.begin() + sz, stk.end()};
     for (auto x : cont) val[x] = -1;
      cb(cont); stk.resize(sz);
   } else val[node] = low;
    return low:
 for (int i = 0; i < n; ++i)
   if (val[i] != -1)
     dfs(i);
```

BCC.h

Description: Finds all biconnected components in an undirected multigraph, and runs a callback for the edges in each. In a biconnected component there are at least two distinct paths between any two nodes. Note that a node can be in several components. An edge which is not in a component is a bridge, i.e., not part of any cycle. HOWEVER, note that we are outputting bridges as BCC's here, because we might be interested in vertex bcc's, not

To get the articulation points, look for vertices that are in more than 1 BCC. To get the bridges, look for biconnected components with one edge

Time: $\mathcal{O}(E+V)$ 3c8daa, 30 lines

```
template<tvpename CB>
void BCC(vector<vector<pair<int, int>>>& graph, CB&& cb) {
 int timer = 0, n = graph.size();
 vector<int> val(n, -1);
 vector<tuple<int, int, int>> stk, cont;
  function<int(int, int)> dfs = [&](int node, int pei) {
   int ret; ret = val[node] = timer++;
    for (auto [vec, ei] : graph[node]) {
     if (ei == pei) continue;
```

```
if (val[vec] != -1) {
      ret = min(ret, val[vec]);
      if (val[vec] < val[node])</pre>
        stk.emplace_back(node, vec, ei);
     else {
      int sz = stk.size(), low = dfs(vec, ei);
      ret = min(ret, low);
      stk.emplace_back(node, vec, ei);
      if (low >= val[node]) {
        cont = {stk.begin() + sz, stk.end()};
        cb(cont); stk.resize(sz);
  return ret;
for (int i = 0; i < n; ++i)
  if (val[i] == -1)
    dfs(i, -1);
```

2SAT.h

Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type $(a \lor b) \land (!a \lor c) \land (d \lor !b) \land ...$ becomes true, or reports that it is unsatisfiable. Returns empty vector if no solution. Negated variables are represented by bit-inversions ($\sim x$).

```
Usage: TwoSat sat(4); // number of variables
sat.Either(0, \sim3); // Var 0 is true or var 3 is false
sat.SetValue(2); // Var 2 is true
sat.AtMostOne(\{0, \sim 1, 2\}); // \le 1 of vars 0, \sim 1 and 2 are true
sat.Solve(): // Returns solution
```

Time: $\mathcal{O}(N+E)$, where N is the number of boolean variables, and E is the number of clauses.

7.2 Flows, Matchings, Matroids

Description: A slow, albeit very easy-to-implement flow algorithm. Mutates graph. Prefer this to DinicFlow when constraints allow.

Usage: while (PushFlow(graph, 0, n - 1)) ++ans;

Time: $\mathcal{O}(EF)$ where F is the maximum flow.

```
bool PushFlow(vector<vector<int>>& graph, int s, int t) {
 vector<bool> vis(graph.size(), false);
 function<bool(int)> dfs = [%](int node) {
   if (node == t) return true;
   vis[node] = true;
   for (auto& vec : graph[node])
     if (!vis[vec] && dfs(vec)) {
       graph[vec].push_back(node);
       swap(vec, graph[node].back());
       graph[node].pop_back();
       return true;
   return false;
 return dfs(s);
```

DinicFlow.h

Description: Quick flow algorithm. If it TLEs on ugly inputs, adapt it to use capacity scaling.

```
Time: \mathcal{O}(V^2E) or \mathcal{O}(E\sqrt{E}) on unit graphs.
```

```

```

7.2.1 Flows with demands

To solve flow with demands where l(u,v) < f(u,v) < h(u,v), first find feasible flow by solving max S'-T' flow on network:

```
 \begin{array}{l} \bullet \ c'(S',v) = \sum_{u \in V} l(u,v) \ \text{for all} \ v \in V \\ \bullet \ c'(v,T') = \sum_{w \in V} l(v,w) \ \text{for all} \ v \in V \\ \end{array} 
• c'(u,v) = h(u,v) - l(u,v) for all (u,v) \in E
• c'(T,S)=\infty
```

Assert that flow equals $\sum l(u,v)$. Next, solve max flow on "residual" graph given flow function (take each edge $(u,v) \in E$ and set c(u, v) = h(u, v) - l(u, v), f(u, v) = f'(u, v). For minimum flow, find max T-S flow on the same network.

7.3 Trees BinaryLifting.h

```

7.5 Math

7.5.1 Number of Spanning Trees

Create an $N \times N$ matrix mat, and for each edge $a \to b \in G$, do mat[a][b]-, mat[b][b]++ (and mat[b][a]-, mat[a][a]++ if G is undirected). Remove the *i*th row and column and take the determinant; this yields the number of directed spanning trees rooted at i (if G is undirected, remove any row/column).

7.5.2 Erdős–Gallai theorem

A simple graph with node degrees $d_1 \geq \cdots \geq d_n$ exists iff $d_1 + \cdots + d_n$ is even and for every $k = 1 \dots n$,

$$\sum_{i=1}^{k} d_i \le k(k-1) + \sum_{i=k+1}^{n} \min(d_i, k).$$

Geometric primitives

LineInter.h

Description:

products up to $O(X^3)$. Both vector variant and line variant are present.

```
"Point.h", "Line.h"
Point LineIntersection(Point a, Point b, Point p, Point q) {
  double c1 = det(a, b, p), c2 = det(a, b, q);
  assert(sgn(c1 - c2)); // undefined if parallel
  return (q * c1 - p * c2) / (c1 - c2);
tuple<T4, T4, T2> LineIntersection(Line m, Line n) {
 T2 d = (T2)m.a * n.b - (T2)m.b * n.a; // assert(d);
 T4 x = (T4)m.c * n.b - (T4)m.b * n.c;
 T4 y = (T4)m.a * n.c - (T4)m.c * n.a;
  return \{x, y, d\}; //(x/d, y/d) is intersection.
```

SegInter.h Description:

If a unique intersection point between the line segments going from a to b and from c to d exists then it is returned. If no intersection point exists an empty vector is returned. e2e If infinitely many exist a vector with 2 elements is returned, containing the endpoints of the common line segment. Does \$1 products up to $O(X^3)$.

"Point.h", "OnSegment.h" vector<Point> SegInter(Point a, Point b, Point c, Point d) { auto oa = det(c, d, a), ob = det(c, d, b), oc = det(a, b, c), od = det(a, b, d): / Checks if intersection is single non-endpoint point. **if** (sgn(oa) * sgn(ob) < 0 && sgn(oc) * sgn(od) < 0) **return** {(a * ob - b * oa) / (ob - oa)}; set<Point> s; if (OnSegment(c, d, a)) s.insert(a): if (OnSegment(c, d, b)) s.insert(b); if (OnSegment(a, b, c)) s.insert(c); if (OnSegment(a, b, d)) s.insert(d);

LineDist.h Description:

return {s.begin(), s.end()};

Returns the signed distance between point p and the line containing points a and b. Positive value on left side and negative

on right as seen from a towards b. Does products up to $O(X^3)$.

WARNING: If a = b nan is returned, although don't rely on that. 32cf2c, 7 lines

double LineDistance(Point a, Point b, Point p) {

```
return det(a, b, p) / abs(b - a);
// Projects point p on line (a, b)
Point ProjectPointOnLine(Point p, Point a, Point b) {
 return a + (b - a) * dot(p - a, b - a) / norm(b - a);
SegDist.h
Description:
Returns the shortest distance between point p and the line
segment from point s to e.
Usage: Point a{0, 0}, b{2, 2}, p{1, 1};
bool onSegment = SegmentDistance(p, a, b) < EPS;</pre>
                                                      e35a3d, 12 lines

  return (r < 0) ? a : (r > 1) ? b : (a + (b - a) * r);
OnSeg.h
Description: Returns true iff p lies on the line segment from s to e. Use
(segDist(s,e,p)<=epsilon) instead when using Point<double>.
"Point.h"
bool OnSegment(P s, P e, P p) {
  return sgn(det(p, s, e)) == 0 \&\& sgn(dot(s - p, e - p)) <= 0;
LinTrans.h
Description:
Apply the affine transformation (translation, rotation and
scaling) which maps (p,q) \to (fp,fq) to point r.
                                                       1d3397, 3 lines
Point LinTrans(Point p, Point q, Point fp, Point fq, Point r) {
    return fp + (r - p) * (fq - fp) / (q - p);
8.2 Polygons
```

PolyCenter.h

Description: Computes the center of mass of a polygon.

Point PolygonCenter(vector<Point> P) { int n = P.size(); Point 0 = 0.; ld A = 0.; for (int i = 0, j = n - 1; i < n; j = i++) { 0 += (P[i] + P[j]) * cross(P[j], P[i]); A += cross(P[j], P[i]); 0 = 0 / 3. / A;return 0;

InsidePolv.h

Description: Returns true if p lies within the polygon described by the points between iterators begin and end. Returns 0 if on polygon, 1 if inside polygon and -1 if outside. Answer is calculated by counting the number of intersections between the polygon and a line going from p to infinity in the positive x-direction. The algorithm uses products in intermediate steps so watch out for overflow. If points within epsilon from an edge should be considered as on the edge replace the line "if (onSegment..." with the comment bellow it (this will cause overflow for int and long long). Time: $\mathcal{O}(n)$

}</pre>
```

ExpandPoly.h

Description: Expands the edges of a polygon with some delta d. To shrink, call with d < 0.

Time: $\mathcal{O}(N)$

WARNING: Resulting polygon might self-intersect for big values of d

PolyCut.h

Description:

Returns a vector with the vertices of a polygon with everything to the left of the line going from s to e cut away.

Usage: vector<Point> p = ...;
p = PolygonCut(p, Point(0, 0), Point(1, 0));

WARNING: Result might contain degenerations when applied to a concave polygon.

Voronoi.h

Description: Determines the voronoi cell of a point with a list of other points. to see if the cell is unbounded, check for points with very high coordinates.

```
auto [a, b] = Mediator(p, q);
ret = PolygonCut(ret, b, a);
}
return ret;
```

8.3 Circles

Circle.h

Description: Circle

"Point.h" leeled, 1 lines
struct Circle { Point c; double r; };

LineCircInter.h

Description: Computes the intersection(s) between a line pq and a circle. Can be 0(non-intersecting), 1(tangent), or 2 points

"Circle.h", "LineDistance.h"

93c2d9, 10 lines

CircCircInter.h

"Circle.h"

Description: Computes the intersection(s) between two circles. Can be 0(non-intersecting), 1(tangent), or 2 points.

CircTangents.h

Description: Finds the external tangents of two circles, or internal if r2 is negated. Can return 0, 1, or 2 tangents – 0 if one circle contains the other (or overlaps it, in the internal case, or if the circles are the same); 1 if the circles are tangent to each other (in which case .first = .second and the tangent line is perpendicular to the line between the centers). .first and .second give the tangency points at circle 1 and 2 respectively. To find the tangents of a circle with a point set r2 to 0.

```
}
CircumCirc.h
```

return 2;

Description:

The circumcircle of a triangle is the circle intersecting all three vertices. CircumRadius returns the radius of the circle going through points a, b and c and CircumCenter returns the center of the same circle.

057e5e, 20 lines

```
double CircumRadius(Point a, Point b, Point c) {

```

PolyVolume3D.h

Description: Computes the (signed) volume of a polyhedron. Faces should point outwards.

```
T Volume(vector<Point> v, vector<Face> faces) {
  double ret = 0; Point O{0, 0, 0}; // origin
  for (auto [a, b, c] : faces) ret += det(v[c], v[b], v[a], 0);
  return ret / 6;
}
```

8.6 Math

8.6.1 Pick's Theorem

If a polygon has vertices on integer coordinates, then:

$$A = I + B/2 - 1$$

where A is the polygon area, B is the number of boundary points (on vertices + edges), and I is the number of interior points (strict).

8.6.2 Euler's Formula

If a finite, planar graph is drawn in the plane without any edge intersections, and V is the number of vertices, E is the number of edges and F is the number of faces (regions bounded by edges, including the outer, infinitely large region), then:

$$V - E + F = 2$$
$$E < 3V - 6$$

A more general formula for K connected components is:

$$V - E + F = 1 + K$$

Strings (9)

KMP.h

Description: pi[x] is the length of the longest prefix of s that ends at x (exclusively), other than s[0..x) itself. This is used by Match() to find all occurrences of a string.

```
vector<int> ComputePi(string s) {
   int n = s.size();
   vector<int> pi(n + 1, -1);
   for (int i = 0; i < n; ++i) {
      int j = pi[i];
      while (j != -1 && s[j] != s[i]) j = pi[j];
      pi[i + 1] = j + 1;
   }
   return pi;
}

vector<int> Match(string text, string pat) {
   vector<int> pi = ComputePi(pat), ret;
   for (int i = 0, j = 0; i < (int)text.size(); ++i) {
      while (j != -1 && pat[j] != text[i]) j = pi[j];
      if (++j == (int)pat.size())
        ret.push_back(i), j = pi[j];
   }
   return ret;
}</pre>
```

ZFunction.h

Description: Given a string s, computes the length of the longest common prefix of s[i..] and s[0..] for each i > 0!!

```
Usage: ZFunction("abacaba") => \{0, 0, 1, 0, 3, 0, 1\}
Time: \mathcal{O}(N) 9b1f7a, 10 lines
```

```
vector<int> ZFunction(string s) {
  int n = s.size();
  vector<int> z(n);
  for (int i = 1, l = 0, r = 0; i < n; ++i) {
    if (i <= r) z[i] = min (r - i + 1, z[i - l]);
    while (i + z[i] < n && s[z[i]] == s[i + z[i]]) ++z[i];
    if (i + z[i] - 1 > r) l = i, r = i + z[i] - 1;
  }
  return z;
}
```

MinRotation.h

```
int MinRotation(string s) {
  int a = 0, n = s.size(); s += s;
  for (int b = 0; b < n; ++b)
    for (int i = 0; i < n; ++i) {
      if (a + i == b || s[a + i] < s[b + i]) {
        b += max(0, i - 1); break;
    }
    if (s[a + i] > s[b + i]) { a = b; break; }
}
```

return a;

```
AhoCorasick.h
Description: Aho-Corasick algorithm builds an automaton for multiple pat-
tern string matching
Time: \mathcal{O}(N \log \Sigma) where N is the total length
                                                       80641a, 34 lines

T.resize(nodes);
return T;
```

Various (10)

AlphaBeta.h

Description: Uses the alpha-beta pruning method to find score values for states in games (minimax). Works faster if better states are explored first.

```
int AlphaBeta(State s, int alpha, int beta) {
 if (s.done()) return s.score();
 for (State t : s.next()) {
   alpha = max(alpha, -AlphaBeta(t, -beta, -alpha));
   if (alpha >= beta) break;
 return alpha;
```

Hashing.h

Description: Arithmetic mod $2^{64} - 1$. 2x slower than mod 2^{64} and more code, but works on evil test data (e.g. Thue-Morse, where ABBA... and BAAB... of length 2¹⁰ hash the same mod 2⁶⁴). "typedef ull H;" instead if you think test data is random, or work mod $10^9 + 7$ if the Birthday paradox is not a problem.

```
struct H {
 typedef uint64_t ull;
 ull x; H(ull x=0) : x(x) {}
#define OP(0,A,B) H operator O(H \circ) { ull r = x; asm \
 (A "addq %%rdx, %0\n adcq $0,%0" : "+a"(r) : B); return r; }
 OP(+,,"d"(o.x)) OP(*,"mul %1\n", "r"(o.x) : "rdx")
 H operator-(H o) { return *this + ~o.x; }
 ull get() const { return x + !\sim x: }
 bool operator==(H o) const { return get() == o.get(); }
 bool operator<(H o) const { return get() < o.get(); }</pre>
```

10.1 Intervals

IntervalContainer.h

Description: Add and remove intervals from a set of disjoint intervals. Will merge the added interval with any overlapping intervals in the set when adding. Intervals are [inclusive, exclusive).

```
Time: \mathcal{O}(\log N)
                                                      49551a, 28 lines

   if (l != l2) emplace(l2, l);
   if (r != r2) emplace(r, r2);
}
};</pre>
```

ConstantIntervals.h

Description: Split a monoene function on [b, e) into a minimal set of half-open intervals on which it has the same value. Runs a callback cb for each such interval.

```
template < class Func, class Callback, class T>
void recurse(int b, int e, Func&& f, Callback&& cb,
            int& i, T& p, T q) {
  if (p == q) return;
  if (b == e) {
    cb(i, e, p);
   i = e; p = q;
  } else {
    int m = (b + e) / 2;
    recurse(b, m, f, cb, i, p, f(m));
    recurse(m + 1, e, f, cb, i, p, q);
template<class Func, class Callback>
void ConstantIntervals(int b, int e, Func f, Callback cb) {
  if (e <= b) return;</pre>
  int i = b; auto p = f(i), q = f(e - 1);
  recurse(b, e - 1, f, cb, i, p, q);
  cb(i, e, q);
```

10.2 Dynamic programming

KnuthDP.h

Description: When doing DP on intervals: $a[i][j] = \min_{i < k < j} (a[i][k] + a[k][j]) + f(i,j)$, where the (minimal) optimal k increases with both i and j, one can solve intervals in increasing order of length, and search k = p[i][j] for a[i][j] only between p[i][j-1] and p[i+1][j]. This is known as Knuth DP. Sufficient criteria for this are if $f(b,c) \le f(a,d)$ and $f(a,c)+f(b,d) \le f(a,d)+f(b,c)$ for all $a \le b \le c \le d$. Consider also: LineContainer (ch. Data structures), monotone queues, ternary search. **Time:** $\mathcal{O}\left(N^2\right)$

OnlineFFT h

Description: Computes DP of the form $dp[i] = a[i] + \sum_{j < i} dp[j] \cdot b[i - j]$. Result is stored in a. Make sure that size is a power of 2.

void OnlineFFT(vector<ModInt>& a, int a_lo, vector<ModInt>& b,
 int b_lo, int sz) {
 if (sz == 1) return;

Time: $O(n \log^2 n)$ 077e3c, 8 lines

10.3 Debugging tricks

- signal(SIGSEGV, [](int) { _Exit(0); }); converts segfaults into Wrong Answers. Similarly one can catch SIGABRT (assertion failures) and SIGFPE (zero divisions). _GLIBCXX_DEBUG failures generate SIGABRT (or SIGSEGV on gcc 5.4.0 apparently).
- feenableexcept(29); kills the program on NaNs (1), 0-divs (4), infinities (8) and denormals (16).

10.4 Optimization tricks

__builtin_ia32_ldmxcsr(40896); disables denormals (which make floats 20x slower near their minimum value).

10.4.1 Bit hacks

- x & -x is the least bit in x.
- for (int x = m; x;) { --x &= m; ... } loops over all subset masks of m (except m itself).
- c = x&-x, r = x+c; $(((r^x) >> 2)/c) \mid r$ is the next number after x with the same number of bits set.
- rep(b,0,K) rep(i,0,(1 << K))
 if (i & 1 << b) D[i] += D[i^(1 << b)];
 computes all sums of subsets.</pre>

10.4.2 Pragmas

- #pragma GCC optimize ("Ofast") will make GCC auto-vectorize loops and optimizes floating points better.
- #pragma GCC target ("avx2") can double performance of vectorized code, but causes crashes on old machines.
- #pragma GCC optimize ("trapv") kills the program on integer overflows (but is really slow).
- #pragma GCC optimize ("unroll-loops") unrolls loops.
- **#pragma** GCC target ("avx2,bmi,bmi2,lzcnt,popcnt")

Montgomerv.h

Description: Faster ModInt multiplication using Montgomery space. Copy other operators from "ModInt.h" if needed.

WARNING: Using the ModInt wrapper might make the operations slower. Refactor at your own risk.

```
// Set T2 such that (T2)mod * mod does not overflow.
using T = uint32_t;
using T2 = uint64_t;
const int BITS = 8 * sizeof(T); // = 32
const T MOD = 998244353, INV = 3296722945, R2 = 932051910;
```

FastInput.h
```

Description: Read an integer from stdin. Usage requires your program to pipe in input from file.

```
Usage: ./a.out < input.txt
```

Time: About 5x as fast as cin/scanf.

```
inline char gc() { // like getchar()
    static char buf[1 << 16];
    static size_t bc, be;
    if (bc >= be) {
        buf[0] = 0, bc = 0;
        be = fread(buf, 1, sizeof(buf), stdin);
    }
    return buf[bc++]; // returns 0 on EOF
}

int readInt() {
    int a, c;
    while ((a = gc()) < 40);
    if (a == '-') return -readInt();
    while ((c = gc()) >= 48) a = a * 10 + c - 48;
    return a - 48;
}
```
